    - What if we changed our conference abstract instead of being an academic abstract to being a 1 page sheet it might have a figure or whatever on it but it's aimed to be more relevant in industry and it says here is what I studied here is what is important that's it.
    - If an industry member is going to participate they don't write a full paper they write a one page thing that says here is my problem and any other questions I have that need to be answered in order for me to resolve the problem - an excellent little paper that academics can pick up and say let's collaborate on this, it's a great idea.

- Often times I don't present my best work at conference because I had submitted as a journal; I think a lot of people will just publish their B work in conferences instead of their A work and that's not good.
- This morning (at the conference) the ILO guy mentioned action research and action research is a fantastic opportunity for collaboration between academia and research and CIB should be really leading that to.
- With regards to diversity in construction, women tend to go into the planning and design process not out in the actually production phase.

2. Development strategy: What is needed in terms of knowledge, information, tools, concepts and applications to enable the respective systems, processes and technologies to develop from where we are today to where we want to be in the future? Comments around this theme include:

    - Safe design is not just accidents but it is occupational health incidence, ergonomics, and a better work place.
    - Because we look at ethics and morals differently in different countries we can't deal with in exactly the same way all around the world.
    - I would really like to see W099 being more of a one stop shop you know the go to place for whatever health and safety issues you have. The ability to come up with resources that can give currant advice and point to work that is being done.

5. Future Directions

The results and summaries presented here are going to be further analysed and refined through a series of on-line consultative workshops to be conducted April 2015 with the goal of drafting the research roadmap around the four specific aims highlighted in Section 2. A workshop will be held at the 2016 World Building Congress for final validation of the roadmap. Reports on the roadmap will be conducted at every annual W099 meeting beginning in 2017.

6. Conclusions

This paper provides the initial insights to the development of the W099 research roadmap. It is not a complete paper with definitive conclusions as the research is preliminary. The purpose of the research roadmap is to guide the workings of CIB W099. It is not directorial and should never be considered so. The idea is that the collective experiences, expertise and research excellence of the group can be brought to bear on specific goals that will in the long run improve and enhance the safety, health and wellbeing of the communities of which we are all a part. The pre-conference academic debate and the 'Bashing the Heads of Bunny Rabbits' session considered how we as a research community can and should use creative, innovative and fun ‘audience engaging’ approaches to deliver a serious and critical message, how do we make vision zero harm a reality? And where do each of us start on this journey? Just as the medical team (1966 to 1980) took a global and yet focussed approach to the eradication of small pox there are lessons to be learnt on how seemingly unattainable goals can be achieved with a very specific and concerted strategy, using the wide range of skills, cultural diversity and resources available within the group. For example, if we had a goal to ensure that prevention through design was to be a core element of every designers’ education within a set period, then how would we set about achieving it? It is the coming together of researchers’ approaches and specific W099 goals that will successfully deliver the strategy, as we take the research into the classroom and into the field, making it live of the page.

As researchers, individually or in groups we have the capacity to devote time to CIB W099 goals, without compromising individuality or without precluding and non-CIB W099 research projects. Setting in place a 10-year development strategy allows commission members from one conference to the next to review and update the strategy, taking into consideration the evolving world’s needs and the changing worldview. Consequently, a rolling 10-year strategy is created, which with the goodwill and endeavours of W099 will remain relevant and impactful.

Abstract

This paper examines how the regulatory description of elevator technology has developed during the course of Norwegian regulation history. It tells the story of how a particular piece of interaction between a society and its built environment is described and re-described several times before it becomes a stable part of the collective horizon.

The main hypothesis underlying this paper is that the development of regulations in time reflects feedback-loops between the regulating society and the environment it builds for itself. By studying the text of the regulations, one can consequently see how the perspective of the society evolves on the subject of its built environment.

This paper establishes the built object as the pragmatic interface where society must interfere if it wants to have an actual effect on the whole of built environment. The content of society`s interference becomes empirically available in imperative descriptions of the built object - found in building codes.

By carrying out a content analysis of the building codes, along two sets of parameters, we present an analysis of a specific topic in the Norwegian Planning and building Act, as well as the corresponding Technical Regulations, as they unfold in time. One parameter is the specific topic — the regulations' internal categories. The other parameter is the modal force of the normative descriptions, from recommendations via advice to explicit, quantified regulations. The reading provided by these parameters together accentuates how regulations shape the content of the built object as a societal imperative.

Visualized as a series of diagrammatic plot distributions, the analysis combines quantitative (number of plots per theme) and qualitative (modality of statement) perspectives. By adding a timeline that allows us to inspect how the regulatory situation evolves over time (from one

regulatory situation to another), we are effectively adding a reflective component to our understanding of the impact of societal values on built environment.

In addition to the exposition of the regulatory history of elevator technology, the findings present us with an analytical toolset that allows us to access and discuss the interaction between society and built environment as their reciprocity evolve over time.

Keywords: Built environment, building regulations, elevator technology, content analysis

1. Introduction

The interaction between a society and its built environment is a two-way dynamic. We embed information corresponding with our collective needs and agreement into the environment by building.

Containing explicit descriptions of the object, building codes are available sources of society´s imperative actions upon the environment. This information can be studied as individual instances in time, however, when put together and regarded as process, they can be interpreted as feedback-loops – going from built environment back to society.

This study selects one specific topic, namely the description of “lifts and escalators” from the Norwegian building code and analyses its’ development all the way back to the first national building law. The genealogy of “lifts and escalators”, as described in building codes, is presented along a timeline exhibiting when the topic first became a regulatory concern, how it was described, and how the description has developed over time up to present day.

The developmental pattern of the elevator description shows how even an uncontroversial building technology undergoes a development in the regulations before it finds its form. The pattern indicates relations that exist between society and elevator technology, specifically. A fundamental conviction of the authors of this paper is, however, that this pattern permits the unwrapping of more general insights into the nature of the process of regulation as an interaction between a society and its built environment.

In this specific study of Norwegian building codes, we pose the following research questions:

- What happened in the building codes when the elevator come to Norway?
- How did the regulatory description of elevators develop up to its present conditions?
- What genus of interaction does the regulatory development of elevators indicate?

In order to address these questions, firstly, the object is identified as the operative interface of interaction between a society and its built environment. The method section specifies the analytical operations done in this special case study of “lifts and escalator”-descriptions in Norwegian building codes. The findings visualise a time series of regulatory elevator descriptions into a continuous image of societal process. Finally, the findings are discussed in light of the research questions, followed by a summary with recommendations pointing towards future, comparative studies to test the hypothetical answers.

2. Theoretical Framework

Building Projects are inherently social activities (Fallan, 2008). The organisation and execution of such projects represents the collaborative effort of a community. Building projects utilise shared resources like infrastructure to enable acts of adaptation that individuals would be incapable by themselves. Regardless of being informally or formally constituted, this makes them strategic acts (de Certeau, 1980); they provide advantages to action by the manipulation of shared environment. Socially, these actions matter, not only because they are interactions, but because they contribute to ground a social reality in(to) the physical reality by their results.

The effects of a building are shared; they are beyond private interest alone. Even if the physical entity is necessary for embodying the result; a building, as shared reference, matters beyond the interest of the individual and the technology that enables its necessary scale. Buildings have (cognitive) agency in the interdependent, inherently social field of action (Gieryn, 2002). The social significance of buildings exceeds their instrumental aspects. They partake in matters of aesthetical, political and epistemological importance (Kara, 2011).

The notion of a building commonly refers to a physical artefact. To avoid the misunderstanding of reducing the basic unit of the built environment to its purely technological aspect, we refer to the base unit of the built environment with the more abstract term *object*.

It is the long-term interest of the collective that makes a society interfere directly into building projects. Settling local conflicts before they take on more large-scale consequence is a practical interest of any society that wants to remain stable over time. Any social action of the magnitude of building holds potential conflicts of interest. The broadness of its social significance and sheer longevity of a built object adds to the severity of the potential conflict scenarios. A project can be mediated by rules and regulations that solves conflict as they arise; In order to ensure its interest in the future consequences of the built object, however, a society must lay down guidelines before conflict arise — it must anticipate.

To have an actual effect on future environments, society`s interest must be expressed in the interface where content is embedded into environment. It must take the form of descriptions that cannot easily be replaced or translated away among the many concerns and interest that surface within the project framework. To make a difference in the built environment, societal interest must, because it is embedded via the project process, at one juncture of translation become explicit object descriptions in order to be actionable.

The most direct imperative descriptions of the object are found in building codes. Many societal documents and institutions describe the built object, either explicitly or by implication; none, however, do it with the same specificity and imperative force as building codes. In building codes society as a collective efficiently acts upon the object; its description effectively decides whether something is built with societal recognition; building codes define what is legal. To be explicit enough to avoid the risk of mistranslation building codes actually must provide imperatives in the object scale.

Society`s imperative descriptions of the built object interface represents a readily available empirical channel of the interaction between society and built environment. Building codes ideally represent a society embedding content into built environment for societal reasons. It does so in the most efficient scale and in a form that is meant to have an actual effect. The codes are well documented – their availability, impact and explicitness makes them a direct access for the analyst into the interaction between a society, as a collective, and its built environment.

Different societies have been shown to exhibit a varietal of different building regulations (Heijden, 2009). Comparative studies of building codes have been done within the EU (Meijer et al., 2002). The Norwegian code is not included in these studies. It should, however, be directly comparable, and correspondingly valuable, as a case. No studies found focus directly on building codes` explicit description of the object. The Norwegian case explicitly states a social purpose (§ 1-1, Norwegian planning and building Act). This makes it a potential reference point for studying the content a society embeds for societal reasons – that presumably are of a social nature.

Studying how a specific topic in the Norwegian building codes develops over time, provides insight into the dynamic of the interaction it represents. The effect of a building code on environment should over time have an effect (through a change in consensus among the users) back upon the regulations, urging change if the effects are not satisfactory. Modification within a particular topic of description should in theory reflect change in consensus due to a shared, collective experience. Regulation`s effect on the object can be studied in a time series of building codes. By focusing on a delimited part of these time series, a material that normally remains opaque because of its density and historicity, can be laid open in the explicit way it actually effects and have effected the built environment.

Elevators exemplify a conventional building technology. They attract little controversy as a thoroughly regulated building technology. That elevators pose a significant safety risk in case of malfunction or lack of maintenance presumably contributes to this fact. A study of their development into the contemporary situation thus can shed light into the process of how a new invention becomes a conventional, regulated building technology. The manner in which the regulatory description changes would lay bare the formalist aspect of implementing technology into the environment. As the material for future comparison, this process perspective would also help us understand how building regulations play a role in making certain technologies conventional.

3. Method

Methodically, this study is conducted according to a three-part structure: Firstly, it is framed as a case study, consisting of a literary review of Norwegian regulation documents (Yin 2009). Secondly, it is internally structured as a content analysis of these documents *(Blumberg et al., 2014, Krippendorff 2013)*. Thirdly, it visualises the analytical toolset that leads to the findings (*Tufte* 1997, 2006).

A content analysis enables a reading of how building regulations reflect the interaction between built environment and a society by being a method of highlighting how it makes its content (description) explicit. The goal of a content analysis, according to Krippendorf (2013), is to "infer features of a non-manifest context from features of a manifest text". In this study, these telling features are made apparent by displaying an inventory, not only of what (about the object) the building code describes, but also how it describes: How it reflects its purpose, and effects as a societal imperative.

A selective reading of a time series of Norwegian building codes generates the input of this study. Regulatory statements with descriptive reference to the built object demarcate the units of analysis. The object of reference corresponds with the output of a normal normal building project as defined in professional standards (Moe; et al., 2010). This is a delimiting choice made to focus on built regularities rather than exceptions.

Regulation documents covering the top level of building code, specifically, building Acts and technical regulation are the source texts of this content analysis. Every regulatory situation in the history of the Norwegian building code, as defined by the valid Act and its technical regulations, provide a series of descriptions. This corresponds with the acts of 1924, 1965, 1985, 2008, and the technical regulations of 1928, 1949, 1969, 1985, 1997 and 2010. In addition, a substantial supplementary document expanding on fire safety in institutions from 1963 is included. Yearly revisions of the regulations texts are not included in this study. The sources are limited to the mentioned documents with their revisions as they where openly available at lovdata.no, the Norwegian data base of legal material, per October 2015.

The Norwegian building code handily categorizes its description of the built object into topics. Applying topic as an analytic parameter creates a selective reading into the "Lifts and escalators" topic (section 29-9, chapter 29, Act 2008), as all other topics effectively fall outside our analytical frame.

The regulatory descriptions designate different degrees of explicitness to different components of its description. This scale emerges from the linguistic modality a statement is expressed in. Within the language of the building code, a relative degree of explicitness forms a hierarchy that remains opaque in normal reading. These structural "how"-components of the regulatory description actually affect the real world pragmatics of what is built.

By assigning each analysed statement with a linguistic modal degree, the analytical construct re-codes the reading of the regulation to show a relative relation between each statement. This enables a reading of the building code that accentuates the modal aspect. The scale of modal degrees is derived from the actual, present Norwegian Planning and Building Act (2008). As a continuity, legal modalities expresses an interval spanning from vague possibility to singular, unambiguous necessity. In the Norwegian case this correspond roughly with four levels: From making *Recommendations*, it increases to *Cohesive recommendations*, before becoming binary (yes, no) as *Absolute regulations*, all the way up to the most forcefully specific: *Quantified regulations*. This most specific tier describes legal necessity by prescribing intervals (within, below or above) of certain pre-established values to which the built object must correspond to be legal.

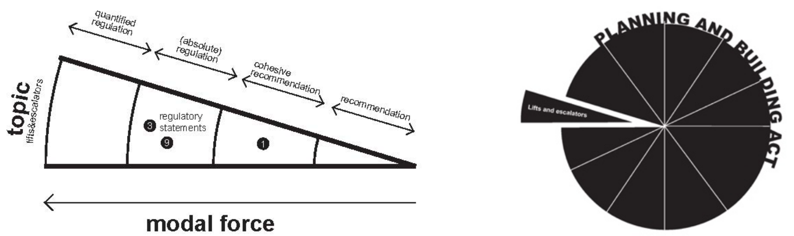
This analytic reading of of a specific topic of description in Norwegian building codes accentuates “how” a topic is expressed. Accentuating the workings of a modal hierarchy within the regulation text reveals the mechanics of (regulatory) expression that corresponds with the pragmatic effect of the building code on built reality. By adding a timeline, the development of descriptive force and explicitness of the topic in question appears.

Because of the imperative signification of the building code, high legal linguistic modality corresponds with forcefulness of the actual effect it prescribes to built reality. Revealing descriptive force unlocks a perspective on the building code`s actual effects. This should correspond with a society`s will to enforce this specific solution out of societal interest in its effect on the built environment. Topic in itself merely designates societal interest, and topic volume only society`s interest`s relevance for settling controversy.

Reference numbers assigned to each unit of analysis ensures replicability to the study. Any individual number can be traced back to a statement in the regulation texts. This makes the procedure replicable and testable. The process relies on human judgment interpreting a grammatical/semantic material. It would not be suitable to an automated procedure. The reliability of the study could be developed in the future, by multiplying the procedure, either to provide Bayesian reliability, or a quantified deviation measurement.

4. Analytic Procedure leading to Findings

Firstly, the body of each regulation text is sorted into topics using the 2008 chapter and sections headlines. The “Lifts and escalators” topic is selected for a specific, in-depth study (Figure 1). Secondly, each individual statement describing the topic is given a number an allotted with a modality according to the scale (also Figure 1).



ic and modality

Thirdly, repeating this to all the 11 unique regulatory situations in Norwegian history since 1924 leaves us with a collection of comparable diagrams showing volume and modality of “lifts and escalators”- descriptions (Figure 2).

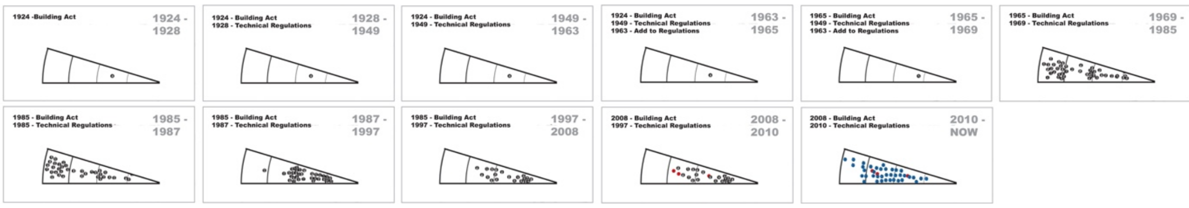


Figure 2: The 11 unique regulatory situations of Norwegian history

Fourthly, the diagrams are distributed chronologically, allowing us to read them as a process. Fifthly, we add a time-line of 100 years and distribute the diagrams on that timeline showing the Norwegian history of elevator regulation. Sixthly, removing the individual diagram, leaving only the plots, the y-axis of the combined diagram now denotes modality, roughly corresponding with descriptive specificity and force (Figure 3). Seventh, and finally, we approximate the plots to a graph by visual analysis; this leaves us with an historical image of the specificity of elevator regulation in Norway (descriptive modality force / time) as our findings.

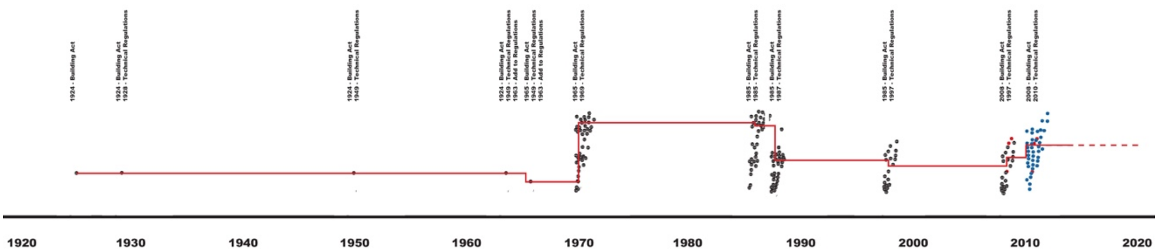

Figure 3: Adapting a graph to the scatter plot

5. Findings

According to the graph in Figure 3, "lifts and escalators" went from barely regulated to very specifically so in 1969. Assuming this occasion corresponds with the period elevators became a proper regulatory concern, that is; a regular building technology and not just a possibility, the introduction of societal interest is characterized by a dramatic increase in modal force (will to specify). At this introduction, the regulation of elevators in built environment appears distinctly specific and forceful.

In 1969, elevator specificity went from barely described to very concerned. The development of regulatory description, however, is characterized by a decline in specificity during the 1980s, that continues in 1997, before a new an uplift in specificity (modal force and volume) appears in the present building code. This new top, however, peaks at a lower level than the peak of specificity characterizing the introduction of the topic into the Regulatory body in the 1960s.

Doing an F´(x) operation on the function (Figure 4), now displaying the finding as degree of modal change/time, displays this tendency even clearer. There appears to be a significant positive change in modality/specificity of description in 1969, followed by negative tendencies in the 80s and 90s, and a new, less dramatic positive tendency leading into the present situation.

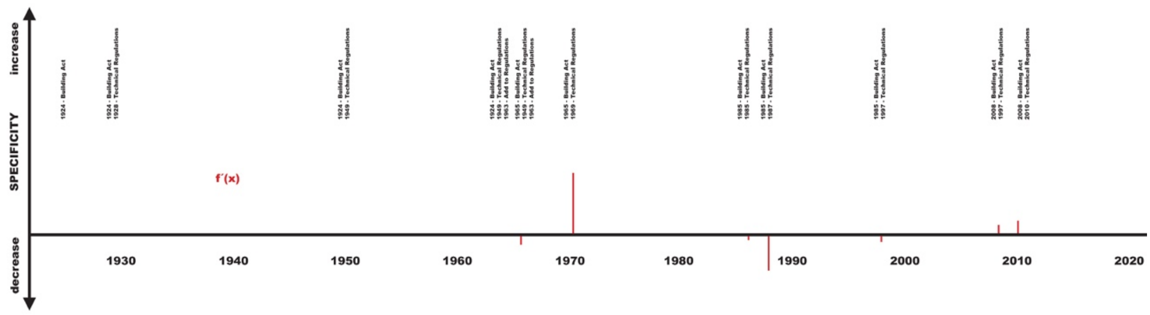

Figure 4: Modal changes in elevator regulations

6. Discussion

The findings clearly indicate that elevators were introduced as a regulatory concern which significant modal force, corresponding with a high degree of specific effects in the built environment. The difference between merely being regulated— a requirement that elevators must be accepted and inspected by officials (the Act of 1924) — to being described in details by the regulation text — down to the diameter of the metal cord used in the mesh in the bottom of the elevator shaft — is quite dramatic.

The modalities of the introductory 1969 technical regulations indicate that strong societal forces took very specific interest in the elevators. Since elevators were relatively new to the general public, whom the building code represent, this force may be the result of either an expert`s perspectives, or that the safety concern (or phobia) connected to the novelty of elevators lead us, as a collective, to limit them to one specific form.

After the initial specificity, our findings show that the regulatory description went through some adjustments, clearly becoming less forceful (and specific), first in 1987 and further in 1997, before they have a resurgence of specificity in 2010. They are yet, however, to reach the same level of force and specificity as the introductory situation of 1969.

The fall in the 80s and 90s, and the new, albeit lower peak in 2010, clearly suggest that the development does not follow a linear pattern. The pattern of the regulatory description of “lifts and escalators” in the Norwegian building code that follows from 1969 is neither a gradual increase in specificity, nor a decrease. According to the findings, elevator regulations rather exhibit a wave-like development. From the present perspective in this historical process, descriptions swing from a high initial state towards a lower overall degree of specificity: From few accepted elevator solutions to several, yet far from laissez-faire.

If this pattern corresponds with an interaction between the regulating society and its built environment, it seems to be characterised by an action-reaction process. A society that embeds content into the build environment by imperative should be expected to adjust these imperatives over time: As a collective, society learns from the consequences of its imperatives through their effects, working back upon its originators from the built environment. The wave-like pattern displayed, if it does represent this interaction of action-reaction, could correspond with a learning process.

Looking at the tendency at display from 1969 and through the present situation, based on the hypothesis that the underlying dynamic driving this development is a learning process, then it seems reasonable to suggest that the descriptions of built environment nested in building regulations, and in this specific case of building technology that is elevators, behave very much like some sort of a collective inquiry. In fact, the Norwegian society poses a very specific hypothesis of the correct (societal) specification of elevators in the build environment in 1969. The collective learns from the consequences of this description, re-state new, less constricting hypothesis in the 80s and 90s, learns from these, and (finally) finds that we need to be more specific in 2010, however not as specific as the first try in 1969 (illustrated by line drawn between peaks in f(x) in Figure 5 below).

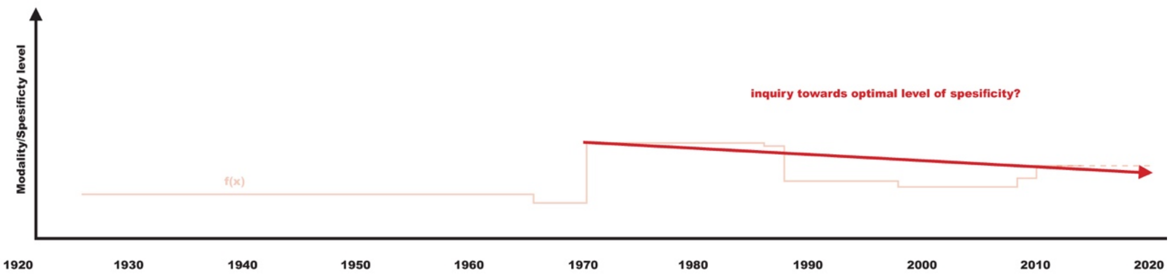

Figure 5: The historical development of Norwegian elevator regulations

If the development of “lifts and escalators” in the Norwegian building code represents a general pattern, the interaction between society and built environment evolves like a big collective experiment. Based in shared interest, Norwegians experiment (try and retry) with the correct level of specification; that is, a beneficiary balance between limits and possibilities of a building technology to meet our collective needs and aspirations; as a society being a temporal continuity. This implies that “the first” description, like the specificity of “lifts and escalator”-regulation in the 1969 is likely to be less than optimal. As a part of a learning process, however, this is just a part of the process. It is adjustment through learning from consequences over time that represents intelligent improvement (and not hitting the spot the first time by share luck).

Learning is not an unlikely explanation of the observed dynamic as it represents a driving force in itself, for intelligent creatures and societies. Learning characterizes the enjoyable process of improvement. Improvement of building codes over time, by collective inquiry is subsequently the collectively enjoyable process towards the most stabilizing, yet dynamic balance of technological augmentation of our environment.

7. Conclusions

This study displays some tendencies in the introduction and development of elevator description in Norwegian building codes over the past 100 years. The main tendency shown resembles a wave-like development from high to lower specificity – a development that as a manifestation of an interaction between a society and its built environment, seems to corresponds with that of a collective learning process.

The scientific contribution of the findings and the toolset developed represents an analytical perspective on the dynamic between society and built environment. This perspective could be of methodical value for regulation professionals, policy makers and technologist alike. It also, however, opens the question of whether these observations of the elevators regulation history are unique to Norway. Few comparative studies cover both the EU and Norway, and for the findings of this study to be generalizable, further studies are in order.

By replicating the analysis to cover building technologies besides elevators, in and outside the Norwegian regulatory situation, the perspective and hypothesis suggested can be tested to see whether "lifts and escalators" regulation represents an oddity or if it embodies a more general pattern in the relationship between society and built environment – that of a reciprocity characterized by continuous inquiry: Of testing, adjusting and improving.

Abstract

Climate change will decrease the heating and increase the cooling energy demand of buildings, and poses challenges in urban planning and construction of buildings. On the other hand, buildings also affect the local climatic conditions. The complex interactions between climate and built environment need to be taken into account in urban planning, designing new buildings, as well as, in renovation of existing buildings.

Two types of past and future hourly test reference weather data sets have been produced for selected locations in Finland, one for considerations of energy demand and the other for purposes of building physics. Using the data sets as input for dynamic building energy simulations, the annual energy demand for heating and ventilation in southern Finland was assessed to decrease by 15-18 % by 2050, and the annual cooling energy demand to increase by 28-34%. Spatial distributions of the future changes in heating (HDD) and cooling (CDD) degree days over the whole country were assessed based on gridded (10 km x 10 km) daily temperature data. By the end of the century in a high emission scenario the HDD will reduce by 1000-2000 Kd compared to the present climate. In a low emission scenario the HDD will be reduced by 500-1000 Kd. The biggest changes will take place in northern Finland and during winter months. The heating period will be shortened by several weeks. The cooling energy demand will remain small compared to heating demand also at the end of the century.

However, these assessments based on meteorological measurements at standard weather stations do not give adequate information about climatic conditions in urban areas. An urban heat island study and simulations with an advanced high-resolution weather model demonstrate how built environment can modify the spatial temperature distribution in Helsinki. Besides affecting the building energy demand, the urban heat island effect intensifies adverse impacts of heat waves on human health. Buildings should be thermally comfortable not only in weather conditions typical for the present-day climate, but also in extreme weather situations and the changing future climate. Comprehensive, integrated information is needed to assess well-being in built environment.

Keywords: heating and cooling demand, climate change, urban heat island, health impacts, weather models

1. Introduction

Ongoing climate change, as well as, climate change mitigation and adaptation policies will have remarkable impacts on built environments. In cold climatic conditions like in Finland, the energy efficiency and reduction of greenhouse gas emissions are main climate related concerns. However, warmer, wetter climate and side-effects of improved insulation of buildings may also have adverse impacts on wellbeing of people, besides increasing the cooling energy demand in summer. Moisture control appears to be challenging in newer buildings both during construction and in use, and mechanical ventilation requires also energy. On the other hand, buildings and changes in land use affect local climatic conditions. Therefore the complex interactions between climate and built environment need to be better understood and utilized in urban planning, and assessed together with sociodemographic changes in order to provide healthy and comfortable built environment for people. Urbanization and socio-demographic changes, like an increasing share of elderly in the population, will further emphasize the importance of integrated, detailed spatial assessments.

Here we mainly concentrate on spatial meteorological information for built environment in the changing climate of Finland. Examples are given about estimates of future chances in the heating and cooling energy demand of buildings in Finland due to climate change: Besides temperature, we briefly describe here changes in other meteorological parameters relevant for built environment such as humidity, precipitation, wind and solar radiation. Furthermore, we demonstrate the urban heat island effect and impacts of built environment on weather and climate in a metropolitan area in Finland. Heat related mortality and regional differences in vulnerability of Finnish population during heat waves are discussed in context to demonstrate the need for integrated information from various sources to be used in urban planning, construction of new buildings as well as renovation of old houses.

In chapter 2 we shortly describe both present and future climate in Finland in general, proceed next to the tailored climate scenarios for building in form of test reference weather data sets and spatial calculations for changes in heating and cooling degree days. In chapter 3 we concentrate on impacts of buildings to the local weather and climatic conditions and in Discussion we reflect on use of applications of these information e.g. in planning green areas in urban areas and preparedness during heat waves.

2. Buildings in changing climate

2.1 Climate variability and change in Finland

The climate of Finland is influenced by the northern geographical position of the country and its location in the western coastal zone of the Eurasian continent. Weather types may vary rapidly depending on the direction of the airstream, and the seasonal and inter-annual climate variabilities are large. Due to cold climatic conditions the energy demand for heating dominates over cooling in Finland. However, the energy demand for cooling cannot be ignored in a warming climate.

The annual mean temperature has already increased over 2 °C since pre-industrialized time in Finland, implying a rising trend of 0.14 °C/decade (Mikkonen et al, 2015). The warming has been more rapid since the 1960s. The observed increasing trend has been higher during winter than summer. The temperature increase exceeds the global average in high latitude countries like Finland. The aim of international climate politics to limit the increase of global mean temperature to 2 °C would mean that the annual mean temperature in Finland would increase by almost 4 °C and precipitation by 10-15 %. In case of high greenhouse gas emissions the annual mean temperature would increase about 6 °C by the end of the century and annual precipitation about 20 % by the end of the century.

The increase in summer temperatures is also expected to manifest itself in longer and more intense heat waves in the future. Based on Ruosteenoja et al. (2013a), summer days with a daily mean temperature above 20°C may occur at the end of the century three to four times as often as during the recent decades. Similar increases are expected for the duration of hot periods.

Along with increasing temperatures, Finnish winters are becoming moister, darker and less snowy. Solar radiation in winter is estimated to decrease by 10-15 %, relative humidity to increase by 2-3 percentage units, and in southern Finland the snow water equivalent will probably be reduced by 70-80 % (Ruosteenoja et al. 2013a). In winter the probability of precipitation in form of rain or sleet will increase, and risks related freeze-thaw damages alter. These changes are thoroughly discussed in the works of Ruosteenoja et al. (2013b) and Vinha et al. (2013).

2.2 Test reference weather data sets

Two types of test reference weather datasets have been developed for Finland, one for considerations of building energy demand and the other for building physics. The former data set aims to describe typical meteorological conditions and the latter critical conditions from the viewpoint of damages in buildings due to moisture.

The impacts of climate change on the demand, delivered consumption and costs of building energy have been assessed by Jylhä et al. (2015) for a typical residential house in Finland. The influences of air temperature, solar radiation, wind speed and air humidity on energy demand were simulated by the IDA Indoor Climate and Energy simulation program, utilizing a recently-developed synthetic Test Reference Year (TRY) hourly weather data as its input (Kalamees et al. 2012). The TRY2012 data set, describing typical climatic conditions in 1980-2009, appeared to work well in capturing the average building energy demand of the example house during that 30-year period. Future TRY data sets were constructed by modifying the TRY2012 time series in accordance with climate model simulations.

Using these future climate projections as input for the building energy simulations, it was assessed that the annual energy demand for heating of spaces and ventilation will decrease by 15-18 % by 2050, whereas the annual cooling energy demand will increase by 28-34%, the lower and upper ends corresponding to the multi-model mean climatic responses to low and high greenhouse gas emission scenarios, respectively. The impacts of the changing climate on the delivered energy consumption and energy cost per m^2 were assessed using three alternative heating systems and two different cooling systems. With other influential factors (e.g., building technology and practices, floor area) held constant, climate change is expected to reduce the amount and cost of energy used in buildings in Finland. The findings can be used to identify potential needs to revise building codes and to improve the energy performance of buildings in order to better mitigate climate change and adapt to its impacts. The results also demonstrate the added value of dynamic building energy simulations compared to the use of cooling degree-days.

The Finnish climate is rather demanding for building physics. Weather datasets containing temperature, relative humidity, wind speed and direction, direct and diffuse solar radiation and precipitation at hourly resolution in 1980-2009 have been produced by Ruosteenoja et al. (2013b) for four locations in Finland. On the basis of the 30-year datasets, two building physics test reference years were selected by Vinha et al. (2013) to represent weather conditions that are particularly critical for the emergence of damages due to moisture in buildings. Corresponding future scenario test reference weather datasets for the building physics purposes were then constructed by employing special treatment for the solar radiation and precipitation data. According to Vinha et al. (2013), climate change increases risks related to moisture behaviour and fault tolerance in several present-day envelope structures.

2.3 Heating and cooling degree days as spatial information

In order to provide spatial information about the anticipated impacts of climate change on heating and cooling demand, use was made of recent past and projected future temperature data on a 10 km x 10 km grid over Finland (Pirinen et al, 2014). The baseline values for the heating (HDD) and cooling degree days (CDD) in the present climate were calculated for the 30-year climatic normal period of 1981-2010, and future scenarios for three 30-year periods (2010-2039, 2040-2069, 2070-2099) were produced for three greenhouse gas emission scenarios (SRES A2, A1B, B1). In operational monitoring of heating demand, an indoor temperature of 17 ^{o}C is used in Finland as the base temperature for heating degree day calculations (S17), and was therefore also applied here. For cooling degree calculations, +18 ^{o}C was chosen as base temperature. Currently in Finland the cooling demand is not monitored operationally.

In the present climate the HDD varies from 3800 Kd in southwestern Finland to 5000-6000 Kd in northern Finland, and heating demand is the highest typically in January. The biggest changes due to climate change are projected to take place in Lapland, where the HDD will be more than 1000 Kd smaller already by middle of the century in the high emission scenario. By the end of the century the heating degree days will be reduced by about 2000 Kd in northern Finland and in southern Finland by more than 1000 Kd (Fig 1, left) in high emission scenario, the reduction is about one third of the value in present climate. In the low emission scenario the heating degree days will be reduced by 500 in southern and 1000 Kd in northern Finland.

Thus, Finland will benefit of climate change through reduced heating energy demand. The changes will take place throughout the heating period and are the biggest in the middle of the winter when measured as absolute values. However, changes in May and September will also be large due to the changes in the length of heating period. In the present climate in southern Finland the length of heating period is about 250 days (8.5 months) and about 300 days (10 months) in northern Finland. By middle of the century the heating period will already be a couple of weeks shorter in southern part and about one month shorter in northern part of the country in case of the high emission scenario (A2). By the end of the century in northern Finland the heating period will be about 1.5 months shorter and in southern Finland 3-4 weeks shorter than in present climate (Fig 1, right).

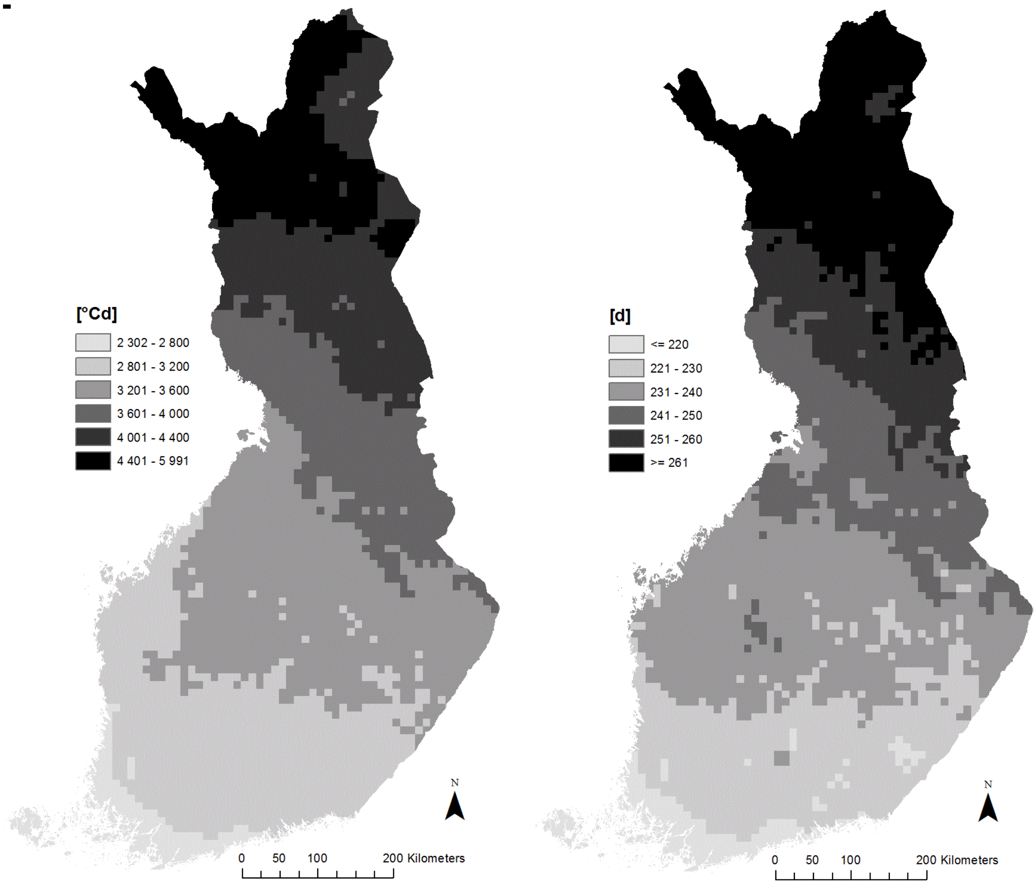

Fig 1. Heating degree days (left) and length of heating period (right) in Finland at the end of the century in high greenhouse gas emission scenario (A2) (Pirinen et al. 2014).

As discussed by Jylhä et al. (2015), the simple CCD method seems to work less adequately for quantitative estimates of future changes in energy demand than HDD does. This is because solar radiation notably affects cooling energy demand in Finland. In qualitative terms, however, CDD can be a useful measure in approximating the spatial distribution of future increases in cooling energy demand, provided that future changes in Finland will be spatially more uniform for solar radiation than for temperature. Obviously, more research is needed for quantitative assessments of future increases in cooling energy demand.

3. Built environment changes climate

3.1 Urban heat island in metropolitan area in Finland

By the end of the decade 2000-2010 the urbanization rate in Finland reached 85%, which means that a little bit more than 4.660.000 Finns live nowadays in cities or city-like settlements. Since the urban heat island effect was recognized in London in the beginning of the 18th century, uncountable numbers of researches (Arnfeld, 2003) have shown that cities and city-like settlements change the climate inside their borders. In general this phenomenon is based on the facts that surface areas absorbing direct solar radiation are greater in cities than in the non-build-up surroundings, while evaporation by trees, bushes and other green areas and sealed surfaces is weaker. Furthermore it is known that every agglomeration of buildings is producing their own heat island effect, at least in some extent. This is also valid for Helsinki where, beside the downtown city centre on the peninsula in the Gulf of Finland, several local centres, like Herttoniemi and Malmi, show their unique urban heat island effect (Fig. 2, Drebs, 2011). Maximum detected air temperature differences between the city centre and surrounding rural area in Helsinki, approximately 9 degree Celsius (Drebs and Vajda, 2006), are in concord with other researches, where the number of city inhabitants has been correlated with the greatest urban heat island intensity (Oke, 1973).

In the changing climate the human well-being in cities will arise as an important concern for inhabitants, city planners and decision-makers. Due to demographic changes, and temperatures differences in urban areas, questions on how to handle the changes in cooling and heating energy demand will become more actual. In order to mitigate adverse impacts of urban heat island, green infrastructure (green roof, green walls, allotment garden, parks, avenues) and natural ventilation corridors need to be considered in city planning.

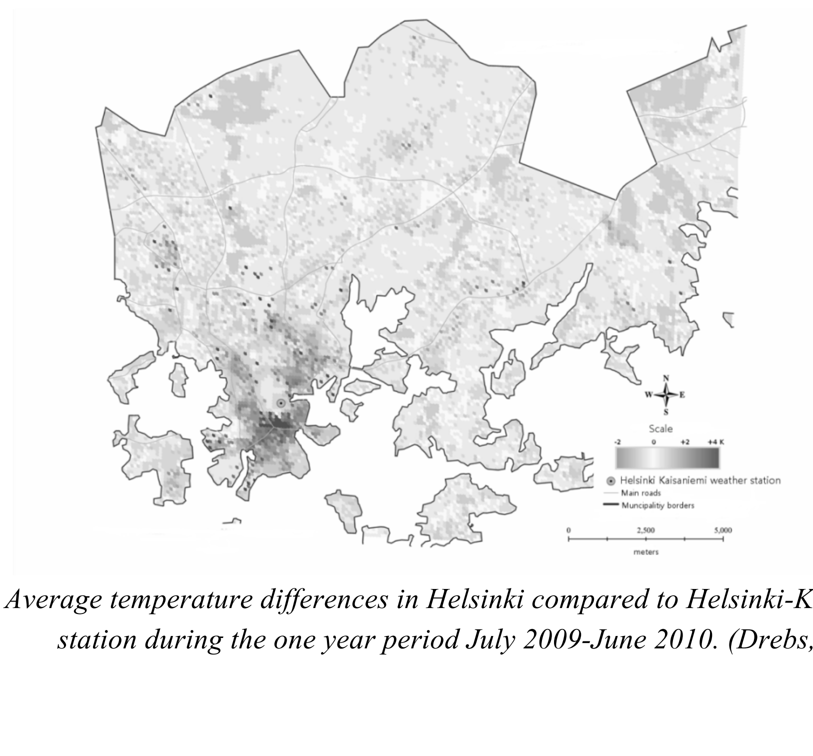

Fig. 2. Average temperature differences in Helsinki compared to Helsinki-Kaisaniemi weather station during the one year period July 2009-June 2010. (Drebs, 2011)

3.2 Physically-based modelling of the urban effects

In assessing the impacts of global climate change in an urban landscape, a challenge is presented by the fact that climate model output data have a coarse temporal and spatial resolution. Besides, observed weather data representing the present climate conditions do not account for differences between the actual climate in cities and at weather stations that are typically located in open vegetated land (rural or natural landscapes). High-resolution physically-based land surface models, by contrast, account for local characteristics when simulating the exchange of heat, water vapour, and momentum between the atmosphere and the underlying surfaces, as well as the meteorological conditions close to the surface. Examples of the detail added by a land surface model are given in Fig. 3, showing simulations carried by coupling the SURFEX land surface model (Masson et al, 2013) to operational forecasts of the Finnish Meteorological Institute. Surface characteristics including land use, vegetation types, and urban morphology were given on a grid of 500 m by 500 m.

The upper two panels of Fig. 3 show the temperature in the afternoon on a warm and sunny summer's day. The temperature above the roof-top level, shown to the left, is a 36-hour forecast by the operational HARMONIE system, based on the AROME atmosphere model (Seity, 2011), here applied on a 2.5 by 2.5 km grid. The spatial pattern is in this case entirely dominated by the land-sea contrast. This contrast is prominent also closer to the ground and in the street canyons (SURFEX: upper left), but there is additional spatial variability, which can be related to the surface characteristics (not shown): the warm (dark) spots are found over densely built areas where the cooling effect of evaporating moisture is small, while fields, forests, and water bodies are relatively cool.

The lower two panels of Fig. 3 show corresponding data for a cold winter's day. Above the roof tops (left), the pattern is again dominated by the land-sea contrast, but with opposite sign compared to the summer case: the ice-free sea is now warmer than the land. As in summer, the land sea contrast is prominent also near the ground (right), and, as in summer, the land use and surface characteristics again give rise to additional spatial variability. Dense urban areas are again relatively warm, owing now mainly to the heat released from buildings and traffic (urban heat island, see Sec. 3.1) while forests and field remain colder.

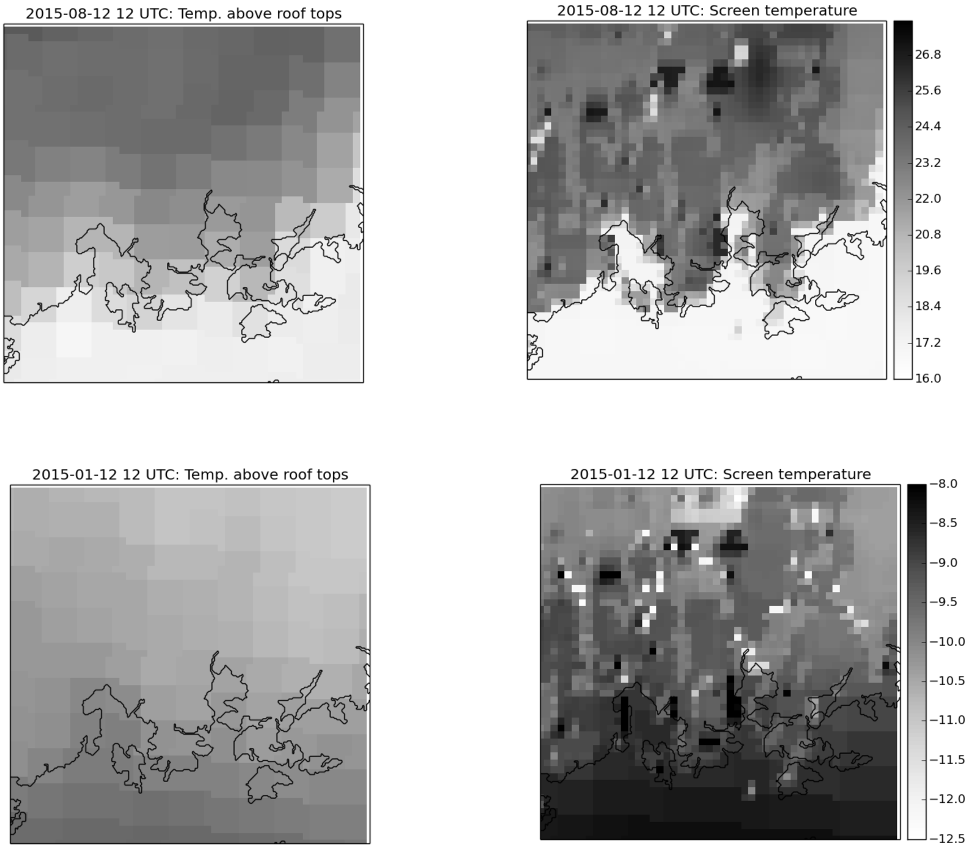

Fig. 3. Examples of the influence of a built-up environment on temperature in summer and in winter. The upper panes show the temperature (degrees Celsius) around the Helsinki region at 12 UTC on the 12th of August 2015. Left hand side: operational 36-hour forecast above the roof top level, right hand side: SURFEX model at screen level. Lower panels: as the upper ones, for 12 JTC on the 12th of January 2015.

4. Discussion

The energy efficiency of the buildings and the climate policy have been the main motivation for the heating and cooling energy projections and their spatial assessments presented here. However, use of the climate information could be further extended for the benefit of sustainable development and quality of life of habitants in urban areas. Climate data, socio-demographic and building stock data can be compiled and studied in more comprehensive way than often currently done. Such comprehensive considerations should be taken into account both in renovation of old building stock and in planning and construction of new urban areas and buildings.

Most of Finland is sparsely populated and, thus, most of both heating and cooling energy is actually needed in southern Finland. For monitoring the development of energy efficiency in Finland, and reporting heating demand of buildings to EU-level with one figure only, we also calculate annual average HDD which is weighted according to the population distribution over Finland. More accurate energy demand assessments might be obtained by combining spatial weather and climate information with the detailed building stock information and population distribution and their future scenarios.

In spatial planning it is important to recognize areas with vulnerable population groups and functions like nursing facilities during extreme weather conditions. Vulnerability to temperature extremes varies depending on socio-economic and demographic distribution and changes in them, e.g. on the proportion of elderly in the population. During the heat waves 2010 and 2014 in Finland about 300 extra deaths took place. According to Kollanus and Lanki (2014) the impact of hot weather can be seen in causes of deaths due to cardiovascular and respiratory diseases, mental disorders and nervous system diseases among elderly. In that study nursing facilities especially were found to have increased mortality during heat waves.

We demonstrated the urban heat island effect in the present climate of Helsinki. As a following step, it would be important to make multi-disciplinary studies to provide information on spatial distribution of population vulnerability (age distribution, housing) to temperature extremes in urban areas. Good examples of such studies are made e.g. in London and Hamburg (Wolf and McGregor, 2013; Schoetter et al., 2013). Recognition of vulnerable areas within the biggest cities in Finland could be utilized not only by urban planners but also by other authorities such as health and rescue authorities, and security of supply.

Furthermore we demonstrated using weather models how buildings can impact the local climate. These kinds of assessments could be utilized in planning of new areas. The efficiency of green infrastructure in minimizing the negative impacts of urban heat island can be studied with the help of such a model. The intensity and extent of the heat island vary according the weather patterns. The weather prediction models are continuously improving both in spatial and time scales and future weather service may be able to provide more detailed forecasts for daily technical building services.

Due to the Finnish long heating period, the security of energy supply is important in all weather conditions, especially in rural areas. We have good experiences on the use of weather forecasts in early warning systems in many sectors of society related to power cuts due to wind storms. The utilization of weather forecasts could be improved in preparedness and early warning systems also in cases of heat and cold waves, especially in health sector.

5. Conclusions

Impacts of climate change and complex interactions between climate and built environment need to be taken into account in decision making in urban planning, designing new buildings and in renovation of existing buildings.

Nowadays, climate information is mainly used in assessments of energy demand in buildings, and energy efficiency is a driving force in design of new buildings and renovation of old ones. Besides energy considerations, however, it would be important to assess combined impacts of climate and built environment on the health and well-being of people, as well, and thus improve the quality of life.

In the future the present work can hopefully be extended into systematic inclusion of weather and climate information in urban planning e.g. in multicriteria analysis for decision making in order to compare various alternative plans (Martinelli et al., 2015). Microclimatic simulations in residential area would help in providing healthy and thermally comfortable environment for inhabitants with best possible use of green infrastructure, and distribution of open spaces and buildings both in present and future climate.

Higher resolution spatial weather and climate information together with vulnerability assessments of population in built environment could also be used in preparedness during heat and cold waves. The preparedness would realize as prevention of extra health problems and burden in health care systems. Daily technical building services would benefit from new, improved weather forecasts concepts that are tailored especially for their area of the interest.

Abstract

Building performance simulation has an important role to play in accurate energy efficient design, yet it is widely recognized that over-simplification in the modelling of physical phenomena leads to substantial sources of error. The evaluation of building envelope thermal performance is fundamental to the correct design of energy efficient retrofit solutions. Thermal transmittance (*U*-value) is a widely used and standard calculation method to assess thermal performance of the building envelope. However, simple calculations such as these do not incorporate climatic conditions applicable to the locality of the building. Simple simulations can be composed to account for moisture loading, moisture retention and the direct result of local climate conditions on transient thermal flux and thermal transmittance. This paper presents selected results of a recently completed research project to demonstrate that it is possible to assess moisture content to simulate corrected transient thermal transmittance of external walls using a hygrothermal modelling tool. The hygrothermal responses of cavity walls in a 1970's elderly nursing home in Dublin, Ireland and its components were assessed with a water content chart, linked to the moisture dependent conductivity of materials. The results and discussion presented in this paper highlight a need for the application of hygrothermal simulation tool to design optimum thermal retrofit/upgrade of exterior wall systems in various geographic locations.

1. Introduction

In the last decade the obligation to ‘retrofit’ existing buildings in response to the long-term challenges of climate change and resource constraints has gained increasing significance (Dawson, 2007, Kelly, 2009, Centre for Low Carbon Futures, 2011, May and Rye, 2012). In the last couple of years the EU Directive on the Energy Performance of Buildings (EPBD) was superseded by the Recast EPBD placing a further emphasis on even higher thermal performance and efficiency levels of existing buildings in Ireland. This emphasis has been reinforced by the publication of the new Technical Guidance Document (TGD) Part L 2011 enforcing higher fabric efficiency values on existing buildings. Despite this, Ireland’s greenhouse gas (GHG) emissions including CO_2 are above the European (EU27) average and still rising to levels that will exceed allowances and commitments made for the Kyoto Protocol (Agency, 2015a, Agency, 2015b). Delivering a sustainable retrofitted building project remains a challenge in the industry due to lack of managing knowledge in sustainable construction projects. It has been argued that there is a possibility for substantial carbon emission reduction through appropriate approaches to sustainable retrofit, however, achieving it presents a multifaceted and difficult problem to the industry due to lack of knowledge management (Shelbourn et al., 2006). As 70% of current residential housing being built pre-dating building regulations including extremely poor insulation and energy efficiency levels, energy consumption optimisation and CO_2 emission reduction can be applied through the thermal upgrade of existing buildings to target the highest savings (Kema, 2008, Shelbourn et al., 2006).

Current research recommends further research on the thermal properties of traditional building materials and construction components; improvements to the thermal transmittance calculations; and a standardised methodology for in-situ measurement of thermal transmittance (Baker, 2011, Künzel, 1998, Little, 2011). Correspondingly, Alliance, (2012) noted that there is little work which describes or quantifies the performance of buildings in relation to energy efficiency while the evidence available is often flawed as it is not based on direct measurement or observation of buildings prior to retrofit work and frequently relies on modelled assessments to prove assertions of improvement.’ It is hoped that this research will inform the on-going deliberation and impact thinking with reference to the measures undertaken to reduce carbon emissions in relation to existing buildings.

The following paper details research into the thermal and hygrothermal performance of an existing residential nursing home in Dublin, Ireland. The nursing home is a 1970’s cavity wall with brick veneer façade, due to be retrofitted in both layout and thermally. A number of solutions were presented for thermal upgrade, with hygrothermal simulation applied to each. The existing building was then analysed using thermography in accordance with ISO 6781:1983.

The research set out to evaluate some of the key issues inherent in the standard calculations using climate and material data to simulate thermal response of cavity walls exposed to the reality of varying climate conditions and locations. Hygrothermal analysis has not previously been tested to aid the simulation of thermal transmission due, most likely to a recent focus on hygrothermal assessment for mould prediction and safe construction. However, this paper presents hygrothermal modelling as an ideal solution to the thermal assessment of thermal upgrade design as a result of pre-established model verification.

2. Moisture & Heat Control by Hygrothermal Simulation

The analysis of the coupling of heat and moisture is known as "hygrothermics" (IBP, 2015b). Building performance modelling began in the 1950's in an effort to calculate net energy demand, analysing the ways in which energy loads could be reduced by building related measures and getting information on the temperature without heating and cooling as this enabled the evaluation of overheating risks (Hens, 2009). Just a handful of models, were able to quantify the air and humidity balances in the building. Instead rough estimates on infiltration and ventilation were used and humidity remained untouched (ASHRAE, 2001).

Building regulations in Ireland recommend that the risks of interstitial condensation should be addressed by following the guidance within TGD Part L leading to British Standard BS 5250:2011. It is recommended here that the risk is assessed with a calculation using the Glaser method, specified in EN ISO 13788:2012. However, this 'conventional' assessment method completely ignores liquid moisture transport, for example as a result of wind-driven rain (WDR). More sophisticated one and two-dimensional full heat and moisture models are available that allow modelling vapour and liquid flow, that are transient in nature, that consider moisture sources such as wind-driven rain, rising damp, initial moisture, sorption and de-sorption, interstitial condensation and surface condensation. They are based on procedures set out in EN 15026:2007, and software packages for such assessment are available, for example MOIST, Match, Wufi, Latenite, Delphin and HygIRC (Sanders et al., 2014).

The first guideline on moisture control analysis by hygrothermal simulation was issued in 2002 by the International Association for Science and Technology of Building Maintenance and Monument Preservation (WTA), an association dealing with preservation and renovation of heritage constructions and rehabilitation of the building stock (WTA, 2002). Five years later the European Standard EN 15026 (2007) which is largely based on the WTA guideline was published (Kunzel, 2014). However, both documents do not contain any information on how to deal with small defects in the building envelope. Parallel to the standard work in Europe a slightly more comprehensive standard on moisture control design has been developed in North-America (BSR/ASHRAE, 2008). As a result of numerous damage cases linked to rainwater penetration into constructions with rendered facades, this standard has been the first that proposed the consideration of the effects of small leaks in the exterior finishes of exposed walls (Cheple et al., 2000).

2.1 Review of Simulation Tools

A report by Hens (1996) showed that 37 programs had been developed for Heat, Air and Moisture (HAM) analysis. A review of hygrothermal models suitable for building envelope retrofit analysis was conducted by Corporation (2003). This review identified 45 hygrothermal simulation tools. Delgado et al. (2010) expanded this figure to 57 hygrothermal modelling tools. This list was reduced to 14 hygrothermal models based on their availability to the general public. A critical review of these simulation tools and their level of complexity can be read in their book: (Delgado et al., 2012). WUFI was used in this research however as it has been validated in the field and laboratory more than other hygrothermal simulation tools.

2.2 WUFI (Wärme Und Feuchte Instateonär - Transient Heat and Moisture Transiency)

WUFI is a family of software products that allows realistic calculation of the transient coupled one- and two dimensional heat and moisture transport in walls and other multi-layer building components exposed to natural weather (IBP, 2015a). The software has been validated by detailed comparison with measurements obtained in the laboratory and on IBP's outdoor testing field (IBP, 2015a). Both one and two dimensional simulation tools have been validated numerous times using data derived from field and laboratory tests (Künzel, 1995). In terms of heat transfer, WUFI takes into account: thermal conduction, enthalpy flow (including phase change), short-wave solar radiation and long-wave radiation cooling (at night).

Vapour-phase transfer is by vapour and solution diffusion while liquid-phase water transport occurs through capillary conduction and surface diffusion. Convective heat and mass transfer is disregarded in WUFI models. In this case a simplified method of calculation of μ has been used for materials:

$$\textit{Vapour resistivity (Vr) x 0.2} = \mu$$

The thermal and moisture conditions and transport in buildings and building components are coupled. It is well known that high moisture levels result in higher heat losses, and the temperature conditions in building components influence the moisture transport. The traditional method for assessing the moisture balance of a building component has been the Glaser method (described in TGD Part L and ISO 13788) which analyses the vapour diffusion transport in the component. However, this method does not account for the capillary transport of moisture and for the sorption capacity of the component, both of which reduce the risk of damage in case of condensation. Furthermore, since the Glaser method only considers steady-state transport under simplified steady-state boundary conditions, it cannot reproduce individual short-term events or allow for rain and solar radiation. It was meant to provide a general assessment of the hygrothermal suitability of a component, not to produce a simulation of realistic heat and moisture conditions in a component exposed to the weather prevailing at its individual location (IBP, 2015b). WUFI software requires standard material properties and moisture storage and liquid transport functions. For boundary conditions, measured outdoor climates – including driving rain and solar radiation – are used.

3. Methodology

The methodology used in this phase of the research is modelled around multi-methodological design, incorporating some qualitative research to allow a fuller piece of research as suggested by Creswell (2009). Data collection and analysis through past and present research by others, along with policy design standards, recorded climate data, housing figures, common external wall constructions, standard design calculation methodologies and non-standard yet required design calculation methodologies corresponds well with and suits the theory of a quantitative methodological approach (Corbetta, 2003, Maxwell, 1998, Maxwell, 2012), the research is structured, performing a series of calculations and recording performance data to produce results which clarify the question. A qualitative approach was used to develop an understanding of the problem and improve methods for the quantitative element of research.

Searches were undertaken of recognised relevant academic and specialist building conservation literature databases through a number of journals and websites of the statutory bodies responsible for the protection of the Irish, UK and European environment. Using the technical indices, namely Technical Guidance Document Part L, the standard calculation methodology for external wall performance was identified as the *U*-value (W/m²K). This document then referenced extended documents explaining *U*-values and materials. Through analysing these documents the *U*-value calculation was evaluated, gaps in the process established, and solutions identified. *U*-value calculations are isolated from climate conditions, and thermal transmittance should be representative of in-situ performance. This problem was identified to be resolved using hygrothermal simulations through WUFI 5.3. The existing wall assembly with varying retrofit solutions applied in a Dublin based maritime climate was assessed using hygrothermal simulations in conjunction with examples set out by (IBP, 2013, Künzel, 1995, Künzel, 1998, Little, 2009, Little, 2011). The existing wall structure was verified through visual inspection through a bore scope along with measurements using metric system as an internationally agreed decimal system of measurement. Thus, the following thermal retrofit/upgrade assemblies were chosen for this study (see , , &).

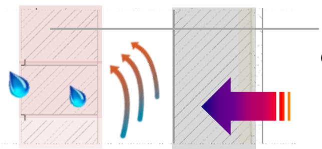

***Fig. 1** - Uninsulated Cavity Wall*

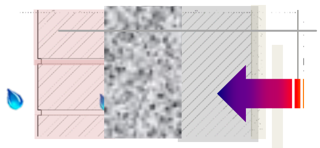

***Fig. 2** – Cavity Fill Cavity Wall*

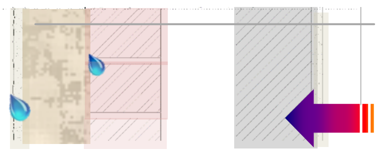

***Fig. 3** – Externally Insulated Cavity Wall*

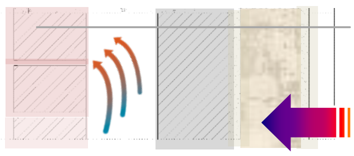

***Fig. 4** – Internally Insulated Cavity Wall*

4. Retrofit / thermally upgraded fabric performance

The fundamental implication of this research was to determine the effect of moisture content in the existing construction. With moisture, conductivity is affected, altering the assumed dry conductivity of materials. In this paper, the overall construction was simulated over 3 years to establish the expected water content in the wall after a significant period of time (as shown in **Fig. 7**). The existing wall thermal transmittance was calculated as 1.688W/m²K following calculation procedures within EN ISO 13788:2012. This was then used as the benchmark to compare against.

4.1 Orientation

Hygrothermal simulation was performed to establish the water content expected in each layer of the basic wall assembly, which then facilitated accurate thermal transmission calculations based on the corrected conductivity of the layers. Firstly, hygrothermal simulation was performed on the existing wall assembly for all 4 geographical orientations using a Dublin maritime climate file acquired from Meteotest (providers of weather, climate and environmental data in Europe). This study highlights the effect of combined wind and rain (wind-driven rain or WDR) on the thermal transmission of the existing wall build-up. For the purpose of this paper, the potential worst case scenario for the case study was analysed. As is demonstrated in ***Fig. 5*** & Table 1, the West façade is presented as the least thermally efficient façade orientation. This is due to a prevailing westerly wind in Ireland, thus driving rain exposure.

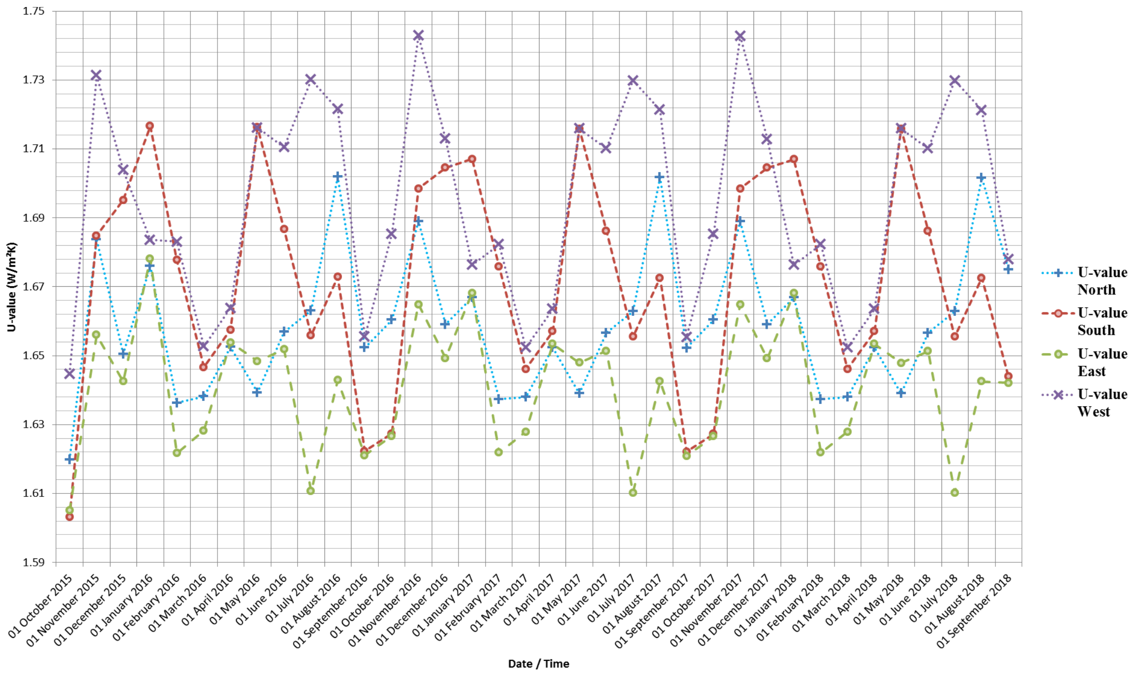

Fig. 5 – Thermal transmittance trend based on orientation. Source: WUFI Simulation.

Table 1. Transient thermal transmission values for all wall types. Source: WUFI Pro 5.3

	Benchmark(W/m²K)	*North (W/m²K)*	*South (W/m²K)*	*East (W/m²K)*	*West (W/m²K)*
Avg	1.688	1.859	1.877	1.824	1.913
Min	N/A	1.801	1.777	1.780	1.835
Max	N/A	1.927	1.953	1.875	1.980

Following the analysis of the influence of orientation on thermal transmission, Table 1 illustrates the benchmark thermal transmittance compared against the average transient thermal transmittance based on expected moisture content. Startlingly, the contrast is quite significant, up to 17.2% higher (poorer) than the traditional thermal transmittance and 13.3% higher on average. According to BS 6946, a significant correction shall be applied when over 3% variation from the original thermal transmittance is encountered. Thus, correction shall be applied to the thermal transmittance in this case.

As mentioned, the existing uninsulated wall assembly must be simulated to assess the water content of each layer to formulate the transient moisture dependant thermal transmission. The simulation was performed on a westerly orientated façade over 3 years to derive a pattern of increased, decreased or steady predictable moisture content (see **Fig. 6**).

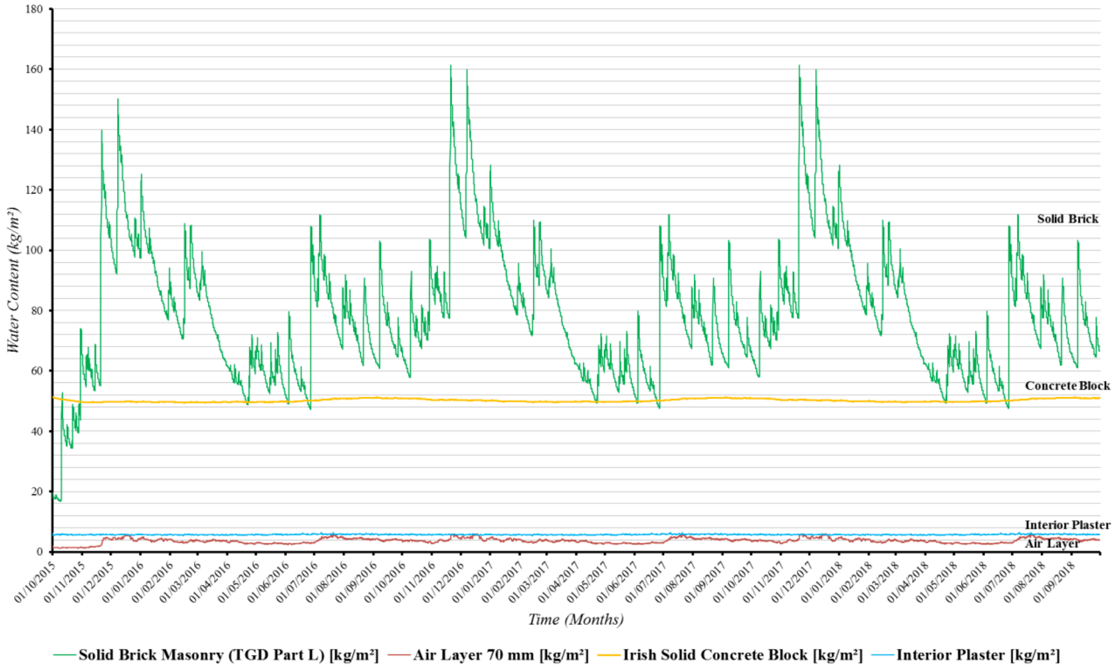

***Fig. 6** – Water content of individual component layers*

Fig. 6 reveals that the wall did not dry slowly or fully. The WUFI postprocessor analyses hourly temperatures and heat flows resulting from the full transient simulation, taking into account hygrothermic conditions in the assembly which result from exposure to climate and occupant behaviour. This includes the effects of variable material properties (in particular, the effect of the variable moisture content on the thermal conductivity), additional thermal transport processes (such as latent heat transport by vapor flows), additional heat sources (such as solar radiation), and parameters depending on environmental conditions (such as wind-dependent surface transfer coefficients). The postprocessor also computes a monthly transient thermal transmittance, using the formula

$U = (-Q) / \Delta Ta$ where, *ΔTa [K]: Monthly mean value of temperature difference between indoor and outdoor air temperature*

5. Retrofit Assembly Simulation

According to TGD Part L 2011, only material alterations require a backstop or target thermal transmittance for existing buildings of 0.60W/m²K. As a target emanating from the overall research, the backstop thermal transmittance as set out in the Sustainable Energy Ireland (SEAI) Better Energy

Homes Scheme for thermal upgrade funding were selected as design targets of 0.27W/m²K for all forms of thermal upgrade treatment to external walls.

Thermal transmittance targets were achieved through the application of insulation on the existing wall assembly. To accurately predict the moisture content and thermal transmittance, accurate material properties were compiled in *Table 2* from (Department of the Environment, 2011), WUFI Pro 5.3, and material manufacturers directly.

Table 2 Table of material data for simulations

Wall Types	***Insulation Material Applied***	***Conductivity (W/mK)***	***Specific Heat Capacity (J/kgK)***	***Bulk Density (kg/m³)***	***Porosity (m³/ m³)***	***Water Vapour Diffusion Resistance Factor***	***Insulation Location***
WT1	Kingspan EPS White	0.038	1130	14.8	0.95	60	***Internal Insulation***
WT2	Gutex Wood Fibre Board (thermoroom)	0.038	2100	131	0.91	2	
WT3	Calsitherm Calcium Silicate	0.057	1303	222	0.92	5.4	
WT4	Sto Perlite	0.042	850	100	0.96	8	
WT6	Isover Mineral Wool	0.035	840	115	0.95	1	
WT7	EcoCell Cellulose	0.040	2500	70	0.95	1.5	
WT8	Kingspan PIR	0.022	1400	32	0.99	50	
WT9	Kingspan Phenolic	0.020	1880	43	0.95	200	***External Insulation***
WT10	Kingspan EPS White	0.038	1130	14.8	0.95	60	
WT11	Kingspan EPS Platinum	0.031	1130	17	0.95	30	
WT12	Rockwool Façade Mineral Wool	0.038	1030	135	0.953	1.1	
WT13	Gutex Wood Fibre Board (thermowall)	0.039	2100	160	0.90	2.1	
WT14	Kingspan EPS EcoBead	0.033	1200	11.5	0.95	60	***Cavity Fill Insulation***
WT15	Rockwool Mineral Wool EcoWarm	0.039	850	40	0.95	1.1	

These insulation materials were then incorporated into hygrothermal models and simulated over a 3 year time frame in a Dublin based maritime climate.

The water content of the wall assemblies did not drop below 15kg/m³ beyond the first month. So, 80% of wall assemblies exhibited a rising water content which stabilized after 3 years, while the remaining 20% of wall assemblies still displayed increasing water contents. These results indicate a trend which may provide a predictable performance applicable to these wall assemblies. Furthermore, water content may be predicted for each wall assembly as analysed in **Fig. 7**.

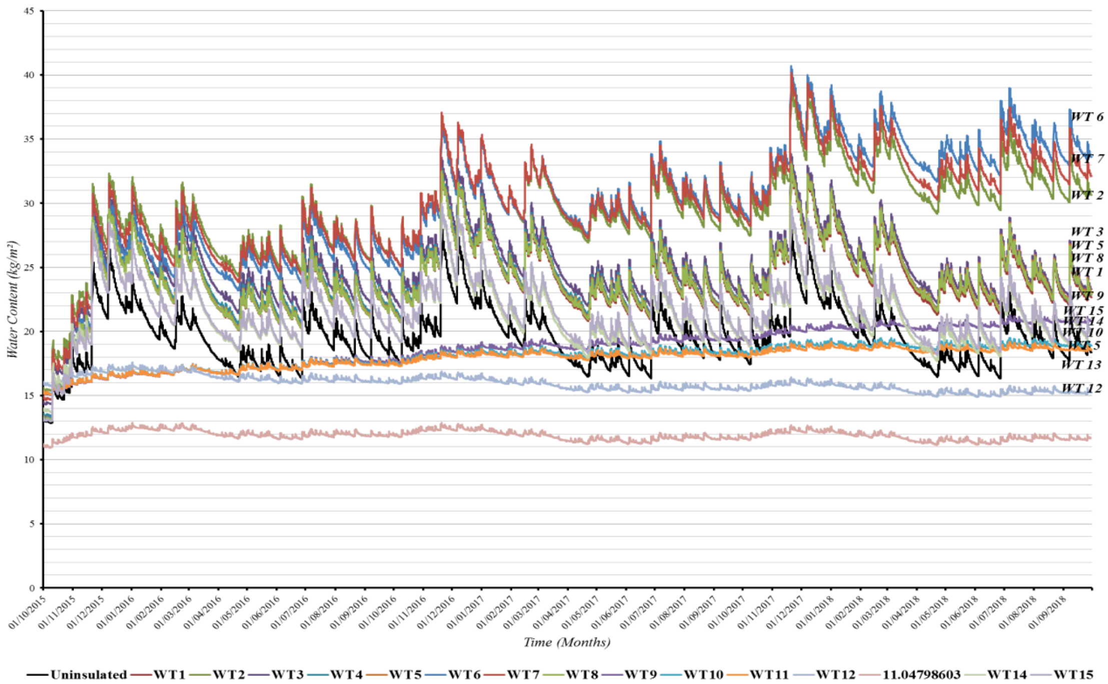

***Fig.** 7 – Water content in each wall build-up. Source: WUFI simulation*

This water content was applied and incorporated to thermal transmission simulations over the same 3 year period in **Fig. 8**.

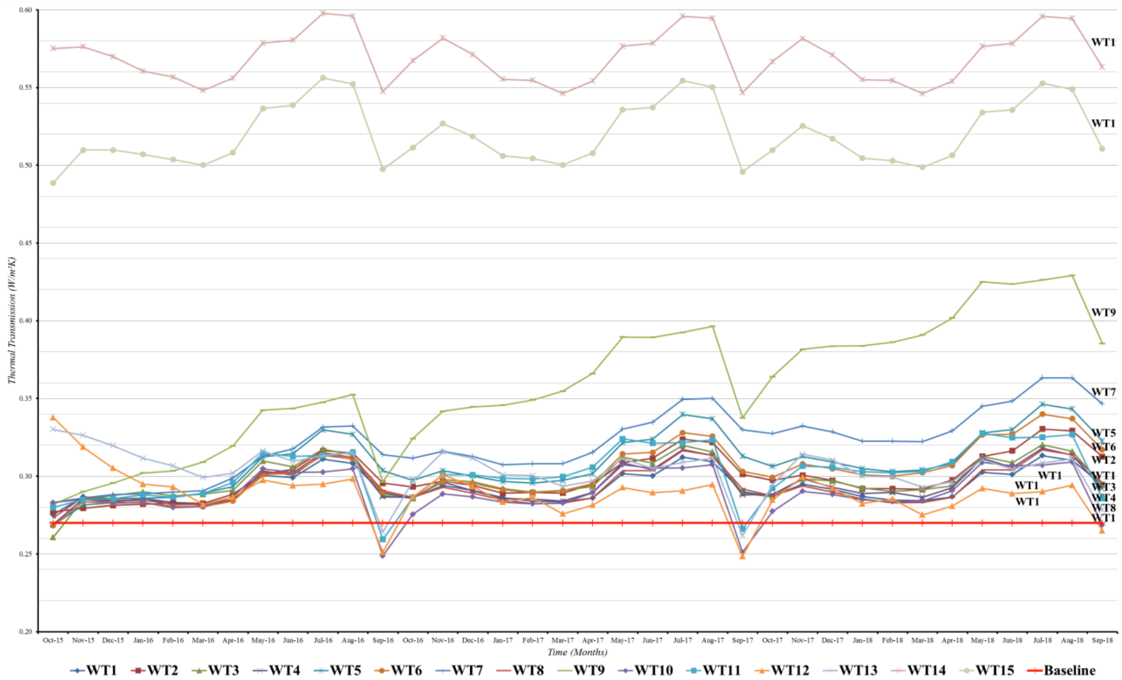

***Fig. 8** – Trend of cavity wall retrofit thermal transmittance. Source: WUFI simulation*

The fundamental here is that the thermal transmittance for each wall assembly varies dramatically as demonstrated through the hygrothermal simulations in ***Fig. 8***. **Table 3** clarifies the findings of ***Fig. 8*** through a chart highlighting the highest thermal transmission.

Table 3 Transient thermal transmission values for all wall types. Source: WUFI Pro 5.3

	WT 1	WT 2	WT 3	WT 4	WT 5	WT 6	WT 7	WT 8	WT 9	WT 10	WT 11	WT 12	WT 13	WT 14	WT 15
Avg	0.300	0.300	0.298	0.295	0.309	0.302	0.321	0.294	0.358	0.289	0.302	0.289	0.304	0.570	0.520
Min	0.277	0.277	0.261	0.269	0.269	0.268	0.283	0.273	0.282	0.249	0.259	0.249	0.262	0.546	0.489
Max	0.330	0.330	0.320	0.318	0.346	0.340	0.363	0.317	0.429	0.309	0.328	0.338	0.330	0.598	0.556

Table 3 confirms the inconsistency between the standard thermal transmission calculation and these simulations. The benchmark thermal transmission of 0.27W/m²K was exceeded by as much as 158% in the case of phenolic insulation at maximum peaks. On average, this translates to 33% greater than the benchmark.

6. Discussion

The finding of this stage of the research suggests that orientation has a significant impact on the hygrothermal performance of an external cavity wall. Correspondingly, the orientation will have a significant impact on the thermal transmittance of the same wall assembly. This means that when designing an external wall, designers should focus the design parameters around the West façade for hygrothermal performance and thermal transmittance in Ireland. Furthermore, the findings from the research identify and highlight the disparity between thermal transmittance from standard calculations and the gap between those and the simulations presented here. It is clear that the existing thermal transmittance calculation methodology is imbalanced with a number of flaws in its composition. This could be addressed using the knowledge derived from this research. To further add to this research, verification through in-situ analysis will be carried out on this case study property. Different techniques can be employed to measure in-situ thermal transmittance such as, for instance, thermographic surveys (Albatici and Tonelli, 2010, Fokaides and Kalogirou, 2011), however, the common in-situ measurement methodology uses thermal flux sensors (Peng and Wu, 2008, Desogus et al., 2011).

7. Conclusions

This paper has reviewed hygrothermal simulations along with standard *U*-value calculations as a method to increase credibility and validity of conclusions resulting from further experimental research. This paper is intended to serve as an introduction to issues emanating from a larger research project in order to encourage researchers to more fully study the topic.

The realm of heat transfer and building physics is a question throughout the AEC (Architectural, engineering and construction) sector, particularly within retrofit and refurbishment. This has been confirmed through an examination of previous research in the field, accompanied by personal experience. The understanding gained regarding the influence of external and internal climactic conditions has already, and continues to enhance the product of this research. Adopting hygrothermal simulations, along with accurate material data analysis has allowed a more concise and defined format of information to be assessed. Through the trawling through previous literature available on AEC research, comparable precedent has been established to set a benchmark for results generated from this research

The findings of this paper identify discrepancies between hygrothermally simulated and standard method *U*-value calculations. The effect of moisture, wind and solar radiation may cause the thermal performance gap illustrated in the simulated assemblies versus the standard method *U*-value. Thus, this paper offers a source of information for researchers and designers exploring the performance of external walls to anticipate best practice detailing and in-situ thermal performance values.

Modelling the wall assemblies, with different porosities, moisture storage capacities and liquid water transport coefficients along with accurate climate data gave very different calculated moisture contents and correspondingly, a corrected thermal transmittance. It is clear that, if advanced hygrothermal models in accordance with EN 15026:2007, such as WUFI, are to be used to carry out routine assessments of moisture conditions and *U*-values in building structures, considerably more construction material data must be made available by manufacturers to achieve realistic simulation results.

Effective research on detailed heat transfer in construction is difficult and necessitates skill and knowledge that is rarely provided in AEC research programs. To understand the full range of challenges faced when doing research, graduate AEC students should take at least one course on building physics, preferably one that covers both heat and moisture control incorporating material and climactic influence.

Building a Prosperous Urban Future with Reflective Roofing

Kurt Shickman,
Global Cool Cities Alliance
(email: kurt@globalcoolcities.org)
Stanley Graveline
Sika Corporation
(email: graveline.stan@us.sika.com)

Abstract

The great challenge of the next 100 years is to remake our rapidly growing cities into structures that can stand up to environmental changes with residents that are healthier, happier, and more prosperous than previous generations. We often do not think about the roofs above our heads, but making thoughtful materials choices on urban rooftops is a critical, readily-implementable strategy to help meet our new urban challenges. Roofs comprise over 25% of urban space and are readily accessible and easy to upgrade relative to other urban sustainability interventions. With roofing technologies that are currently available, cities can improve their biodiversity, reduce rising urban temperatures, improve health and quality of life, and defend against high energy costs and power blackouts.

One of the key sustainable roof technologies in the market today are reflective, "cool" roofs. Reflective roofing is an ancient concept achieved with modern technologies that have been growing in the market over the last 20 years. Reflective roofing is a cost-effective and easily deployable strategy to cut cooling energy demand by up to 20%, reduce temperatures in and around buildings, improve air quality and health, and cancel the warming effect of atmospheric greenhouse gases. This paper will provide building owners, government officials, and corporate decision-makers with:

1. the tools to quantify the benefits and costs of reflective roofing for buildings, communities, cities, and the planet;
2. an understanding of the available reflective technology options and a look forward at cutting-edge technologies that will be on the market in the next few years;
3. a roadmap for implementing reflective roofing in a variety of contexts via a detailed review of the most successful policies and programs worldwide that have helped spur local adoption of cool roofs including building and energy code requirements, construction specification requirements, green workforce development, and innovative public information campaigns.

Keywords: cool roofs, reflective roofs, urban heat islands, energy savings

1. Introduction

The parallel challenges of warming global temperatures and a mass migration from rural to urban spaces highlight the importance of improving the sustainability of cities. The benefits of sustainability to urban quality of life, economies, energy use and health are well understood, but even leading cities face difficulties in effecting real change quickly in their complicated and interconnected urban ecosystems. An effort to making smarter choices about roofs, such as using more solar reflective materials, can significantly and immediately benefit efforts to enhance the sustainability of the world's urban spaces. This paper will review the benefits, costs, and technologies available to implement cool roofs and describe a few examples of cities that have used reflective roofing to save energy, cut energy bills, improve grid reliability, cool urban heat islands, and improve the health and social welfare of its citizens.

2. Roofs are a platform for urban sustainability

2.1 Good roofs make sustainable cities

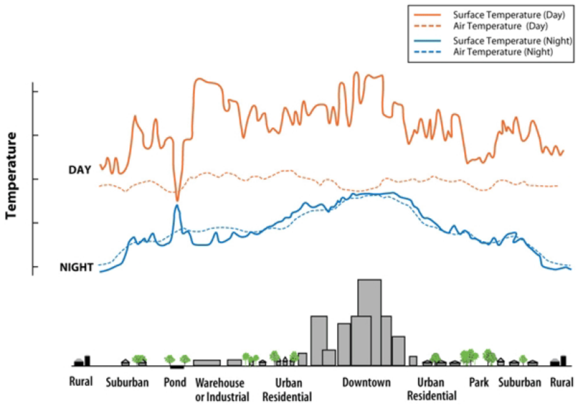
While the average person doesn't give it much thought on a regular basis, roof space is an important platform for urban sustainability efforts. Akbari (2008) found that roofs made up between 25% and 35% of the overall urban fabric in the studied cities. This is a significant amount of urban space that, if upgraded with reflective roofing, vegetation, solar power, or some combination, could drive benefits worth between $0.40 per square meter and $4.33 per square meter in the form of energy savings, reduced health care and storm water management costs, per Kats (2015).

Implementing sustainable roofs can rapidly change cities. Policy makers and building owners have more opportunities to upgrade the sustainability of roofs than other building components or pavements. Roofs are replaced every 15-20 years on average – a replacement rate of 5-7% per year. The benefits to energy use, air quality, health, urban economies, and global climate change mitigation of better roofing start the minute they are installed.

2.2 Urban heat is the defining sustainability challenge for the 21st century city

As Figure 1 from Zhang (2010) shows, cities tend to be an average of 4 to 6 degrees Celsius hotter than rural areas. This phenomenon, known as the urban heat island or UHI, is the result of several factors. Cities are less vegetated relative to rural areas. Buildings block or slow natural wind patterns that would help move heat. Cities are hubs of human activity that generate heat. The biggest contributor to urban heat islands, however, is the predominance of dark, impermeable roofs and pavements that absorb solar energy and radiate heat. UHI is both a day-time and night time phenomenon. Indeed, Climate Central (2014) found that night-time UHI can exceed 20 degrees.

The world is in the midst of a rapid urbanization. The United Nations reports that the percentage of the world's population living in cities will grow from 50% today to 80% in 2050 – all moving into urbanized space that makes up less than 2% of the earth's surface. Oke (1973) and Georgescu (2013) found that the increase in urban density and city size exacerbates all of the factors that cause UHI. Currently, excess urban heat is rising at twice the rate of global average climate change.



Overheated cities experience a number of negative impacts that affect almost every aspect of urban life.

Figure 1: Temperature differences between different levels of urbanization. Source: NASAUrban heat leads to increased energy consumption

Solar energy absorbed by buildings converts into heat energy that is either transferred inside the building or blown off the roof to heat the surrounding air. For buildings with environmental controls, excess heat leads to an increase in cooling energy demand. In general, the relationship between temperature and city demand for electricity resembles a hockey stick. Below a threshold air temperature, typically between 24 to 27 degrees Celsius, daily energy demand is relatively constant. Demand for electricity spikes dramatically as temperatures rise above that threshold. Akbari (2001) indicated that peak electricity demand increases by 2 to 4 percent for every 0.5 degrees Celsius increase in temperature above a threshold of about 15 to 20 degrees Celsius. In New York City, for example, electricity consumption is 29 percent higher on a 32 degree Celsius day compared to a 26 degree Celsius day. The demand for cooling is generally highest during peak electricity consumption hours, the late afternoon and early evening. Akbari (2005) found that the UHI-related increase in air temperature is responsible for 5 to 10 percent of U.S. peak electric demand.

2.2.1 Urban heat reduces air quality

Decreased air quality is one of the most far-reaching effects of UHIs. Poor air quality, in which the ozone levels and levels of small, inhalable airborne particles (PM-2.5) from nearby coal plants are high, is detrimental to public health and the environment. The World Health Organization (WHO) estimated 21,000 premature deaths per year occur across 25 European countries because of high levels of ozone (Amann et al. 2008). WHO further estimates that 14,000 respiratory-related hospital admissions in Europe are directly due to high ozone levels.

Urban air quality influences and is influenced by a city's temperature. An increase in temperature corresponds to the rate at which ozone feed stocks cook into ozone. Akbari (2005) found that for every 1 degree Celsius the temperature in Los Angeles rises above 22 degrees Celsius, smog increases by 5%. Figure 2 from Piety (2007) showed how smog forms in a nonlinear fashion in accordance with the maximum surface temperature at Baltimore-Washington International Airport. Each point represents an 8-hour period. At 27 degrees Celsius, most of the points are below the minimum EPA compliance level of 60 parts per billion (noted with a red line in Figure 2). At and beyond 32 degrees Celsius, the majority of points lie above minimum compliance, meaning the amount of ozone is at dangerous levels.

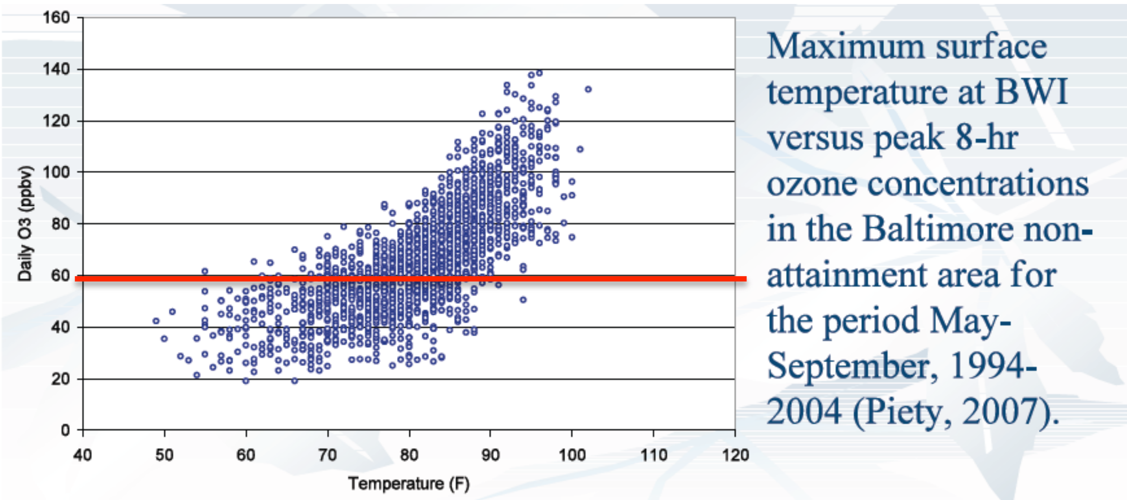


Figure 2: Ozone concentrations by maximum surface temperature. Piety (2007)

2.2.2 Urban heat compromises health

Increased daytime temperature, reduced nighttime cooling, and high air-pollution levels increase health problems and mortality, especially among low-income and elderly populations. In fact, Wong (2012) found that between 1989 and 2000, studies of 50 U.S. cities recorded a rise of 5.7% in mortality during heat waves. The Centers for Disease Control and Prevention (2012) reported that over a 12-year period (1999-2010), excessive heat caused 7,415 premature deaths in the United States. Heat waves in Europe claimed over 52,000 lives in 2003 alone – one of the greatest natural disasters in history.

In addition to causing higher daytime temperatures, urban heat islands keep cities and their residents from cooling off at night. Hotter nighttime temperatures are especially dangerous during extreme heat events. Urban populations are often unable to recover from the daytime heat and become more vulnerable to heat-related health problems in subsequent days.

2.3 Reflective roofing mitigates urban heat

Replacing dark urban surfaces with more reflective and lighter-colored surfaces on roadways, walkways, and roofs is a primary UHI mitigation strategy. The darker a surface, the more potential it has to store heat. A light-colored or reflective surface has a very small potential to store heat because of its high albedo, or reflective ability. Surfaces that reflect solar energy stay cooler, release less heat into the surrounding air, and allow for nighttime cooling in a city.

Cool surfaces are measured by how much light they reflect and how efficiently they radiate heat (thermal emittance or TE). Solar reflectance is the most important factor in determining whether a surface is cool. A cool roofing surface is both highly reflective and highly emissive to minimize the amount of light converted into heat and to maximize the amount of heat that is radiated away.

Most roofs are dark and reflect no more than 20 percent of incoming sunlight (i.e., these surfaces have a reflectance of 0.2 or less); while a new white roof reflects about 70 to 80 percent of sunlight (i.e., these surfaces have a reflectance of 0.7 to 0.8). New white roofs are typically 28 to 36 degrees Celsius cooler than dark roofs in afternoon sunshine while aged white roofs are typically 20 to 28 degrees Celsius cooler.

2.3.1 Benefits of cool roofs to individual buildings

Energy savings potential: Increasing the reflectance of a roof from 0.1-0.2 to 0.6 can cut net annual cooling energy use by 10 to 20 percent on the floor of the building immediately beneath the roof by reducing the need for air conditioning. Levinson 2010 presented an analysis of energy savings in new and old office and retail buildings by U.S. zip code. The analysis found that there are net energy savings in every part of the U.S. (warm and cold climates) except in northern Alaska. Target Corporation, one of the largest American retailers, has experienced net overall energy savings (based on all energy consumed for heating, cooling, lighting and equipment) between 0.5% and 1.0%, depending on location, in their facilities across the USA by specifying white reflective thermoplastic membranes. These energy savings collectively result in several millions of dollars in energy cost savings annually for the company.

Cost savings potential: Levinson 2010 found the average annual net energy cost saving (cooling energy saving minus heating energy penalty) for a white roof on a commercial building in the U.S. is $0.36 per square meter ($0.40 in 2015 dollars). Retrofitting 80 percent of the 2.6 billion square meters of commercial building roof area in the U.S. would yield net annual energy cost savings of $735 million. Globally, cool roofs could save billions of dollars. Kats 2015 evaluated the economic benefits from the installation of cool roofs on municipal buildings in Washington DC and found that cool roofs installed on 2.6 million square meters of municipal roof space would generate net savings to the city of $46.5 million ($17.88 per square meter) in energy cost reductions and avoided health costs.

Improved thermal comfort: In a building that is not air conditioned, replacing a dark roof with a white roof can cool the top floor of the building by 1 to 2 degrees Celsius. Programs to install cool roofs and train proper fan use in Philadelphia led to 3 degree Celsius reductions in indoor air temperature during hot days. These temperature reductions are enough to save lives in extreme heat waves and make non-conditioned work environments like barns and warehouses more usable and comfortable for employees.

2.3.2 Benefits of cool roofs to cities

Reduced summer heat island effect Simulations run for several cities in the U.S. in Akbari (2001) have shown that city-wide installations of highly reflective roofs and pavements, along with planting shade trees will, on average, reduce a city's ambient air temperature by 2 to 4 degrees Celsius in summer months. Reducing urban temperatures makes cities more comfortable and enjoyable to live in and promotes healthier populations.

More resistance to heat related deaths Cool roofs can cool the areas in a building where the risk of death during heat waves is high. For example, there were 739 deaths in the Chicago heat wave of 1995. Virtually all of the deaths occurred in the top floors of buildings with dark roofs. Subsequent heat waves have claimed thousands of lives in the U.S., France, Russia, and elsewhere. Kalkstein 2014 found that 10 percent increases in urban vegetation and reflectivity can reduce mortality during heat waves by 6-10 percent.

Reduced peak electricity demand Cool roofs can improve utility capacity utilization and therefore profitability, reduce transmission line congestion, avoid congestion pricing, and forego the need for additional investments in peaking generation capacity. Rosenfeld et al. (1996) estimated that eliminating the urban heat island effect in Los Angeles a reduction of 3 degrees Celsius could reduce peak power demand by 1.6 gigawatts and save about $175 million per year ($268 million in 2015). Approximately $15 million of that amount was due to more reflective pavements. A 2004 analysis of New York City by the Mayor's Office of Long Term Planning and Sustainability, when electricity averaged $0.165 per kWh, found that a one degree reduction in temperature would cut energy costs by $82 million per year. Electricity prices have subsequently increased by over 20 percent. Hoff (2014) found that peak energy cost savings can be double the base energy savings in many cooler climate zones. Most cost benefit analyses have not quantified this important aspect of energy savings until recently.

Air quality benefits City-wide temperature reduction not only makes cities more comfortable, but also improves air quality because smog (ozone) forms more readily on hot days. Simulations of Los Angeles in Akbari (2001) indicate that lighter surfaces and shade trees could cool temperatures and thus reduce exposure to unhealthy levels of smog by 10 percent to 20 percent. Across the U.S., the potential energy and air quality savings resulting from increasing the solar reflectance of urban surfaces is estimated to be as high as $10 billion per year.

2.3.3 Benefits of cool roofs to the planet

Global cooling potential Akbari 2008 found that replacing the world's roofs and pavements with highly reflective materials could have a one-time cooling effect equivalent to removing 44 billion tonnes of CO_2 from the atmosphere, an amount roughly equal to one year of global man-made emissions. Every 10 square meters of white roofing will offset the climate warming effect of one tonne of CO_2. Assuming the average car emits 4 tonnes of CO_2 per year, the combined "offset" potential of replacing the world's roofs and pavements with highly reflective materials is equivalent to taking all of the world's approximately 600 million cars off the road for 20 years. Put another way, the cooling offset of global reflectivity from cool roofs would cancel the warming effect atmospheric GHG generated by 500 medium-sized coal power plants over the life of the roof.

3. Reflective technology options

3.1 Reflective Roof Technology Options

3.1.1 Roof Types and Cool Roof Options

Cool roofing materials can be divided in to two categories, based on their intended use. Although some technologies are suitable for both applications, generally they are intended for use in either low (≤9.5°, 2/12) or steep (>9.5°) slope installations. The requirements for being considered a cool roofing material vary by category and program. Table 1 summarizes the requirements of the two most prominent programs in the USA, California's Title 24 Energy Code and the Environmental Protection Agency's Energy Star Program.

Table 1. Cool Roof requirements

	Reflectivity		Thermal Emissivity		SRI
	Initial	Aged	Initial	Aged	
California Title 24					
Low Slope	n/a	0.63	n/a	0.75	75
Steep Slope	n/a	0.20	n/a	0.75	16
Energy Star					
Low Slope	0.65	0.5	n/a	n/a	n/a
Steep Slope	0.2	0.15	n/a	n/a	n/a

In the United States, the reflectivity and emissivity (together, their surface properties) of roofing materials are tested according to protocols defined by the Cool Roof Rating Council (CRRC).

The CRRC includes representatives from roofing manufacturers and other experts. The CRRC's standards are recognized in major building energy codes and list both initial/ as received and 3 year aged values.

Cool roofing materials are available in a wide variety of technologies. The most common low slope roofing materials include coatings, single ply membranes and mutli-ply bituminous systems. Coatings are applied over waterproof membrane systems such as dark colored elastomeric single ply sheets or bituminous systems, to provide the desired reflective properties and/or to extend the underlying membrane's service life. Acrylic coatings are most commonly used in these applications. A significant advantage of coatings is that they can be applied to in-place membranes, thereby salvaging the existing materials and negating the need to remove, dispose and replace them, most significantly, the existing thermal insulation. Acrylic coatings have some of the highest initial reflectivity values, with a few products in the low 90 percent range.

Liquid membranes are also available which typically consist of multiple layers of field applied acrylic, polyurethane or other fluid chemistries, incorporating reinforcements. These types of products are particularly beneficial for roofs with difficult access and extensive amounts of roof top equipment and other penetrations concentrated in small, congested areas where roll goods are impractical, such as on high rise buildings.

Combined, thermoplastic single ply membranes, which include both polyvinyl chloride (PVC) and thermoplastic olefin (TPO) materials, represent more than 40% of the low slope roofing market in the United States. The ever increasing demand for energy saving cool roofing materials has been a key driver in their growth over the past years. These materials have initial reflectivity values within the low to the high 0.80 range. They can be applied in a variety of configurations including mechanically attached, induction welded, and adhered. The use of hot air welding to seal the seams of the sheets in roll widths of 8' or 10' allows for high application productivity and low installed costs. Although much less common, some suppliers also offer elastomeric membranes with a white, reflective weathering surface.

Modified bituminous membranes have benefited from the development of reflective granules, and products are now available that achieve reflectivity levels above 0.70. Some metallic surfaced materials achieve values in the same range as thermoplastic membranes and acrylic coatings. Modified bitumen sheets which are typically installed in two or more layers, provide redundancy and a high level of resistance to mechanical damage. A variety of sheets are available depending on the application technique to be used: torched on, adhered with hot asphalt or cold adhesives, or mechanically attached. They are often selected in re-roof situations where their compatibility with existing bituminous materials is advantageous.

Table 2 provides a summary of the initial and three year aged solar reflective properties of the various types of materials available (NOTE: All of these materials have high thermal emittance values, therefore for clarity, only the reflectance values are included)

There are a myriad of cool roofing material options available to choose from. Ryan (2015) noted that there are more than 4,600 products listed in the Energy Star database, and about 2,600 products listed in the Cool Roof Rating Council's database (2015). With products available across the entire spectrum of technologies, performance levels and price there is a cool roof solution for every need and situation.

Table 2: Reflectivity performance ranges for common roofing products.

Type	Number of CRRC Rated Products	Initial Reflectance			Aged (3-year) Reflectance		
		Average	Max	Min	Average	Max	Min
Asphalt Shingles	58	0.26	0.41	0.13	0.26	0.37	0.16
Build-Up and Modified Bitumen Sheet Roofing	84	0.49	0.88	0.25	0.45	0.8	0.23
Concrete/Clay Tile and Slates	429	0.31	0.82	0.08	0.30	0.74	0.1
Field-Applied Coatings	484	0.80	0.94	0.04	0.68	0.87	0.03
Metal Products	1008	0.36	0.77	0.25	0.36	0.74	0.24
Metal Shakes/Shingles (including Granular Coated Metal)	17	0.31	0.46	0.22	0.30	0.44	0.23
Other Roof Products: Fluid Applied Membrane Roofing	10	0.80	0.9	0.42	0.68	0.78	0.43
Single Ply Thermoplastic and Thermoset Roofing	123	0.71	0.91	0.06	0.60	0.81	0.07

There are alternative approaches to achieve similar effects to high surface reflectivity. Some jurisdictions recognize ballasted roofs as alternatives to reflective membranes or coatings in their regulations. Large stone ballast acts as a heat sink, moderating heat transfer into the building. Vegetated or "green" roofs consist of waterproofing membranes covered with growing medium and vegetation. These roofs provide cooling energy savings and help mitigate the urban heat island effect through a combination of shading by the plant media and evapotranspiration. Some major metropolitan areas are incentivizing the use of green roofs as a means to provide some relief to aged, deteriorated storm water sewage systems which often are tasked with handling water volumes far greater than anticipated when they were installed. Although costs continue to decrease over time, they generally have installed costs that are upwards of 50% more expensive than conventional roofing systems.

3.1.2 Design Considerations for Low Slope Cool Roofs

As with all roofing materials and other outdoor surfaces, cool roofs are subjected to various forms of soiling. Research has shown that the degree of soiling tends to level off or plateau after approximately three years of exposure, which is the basis for reporting aged reflectance and emittance values in the most prominent cool roof rating programs. When accounting for the effects of cool roofs in HVAC and other building physics calculations and assessments, only aged values should be considered.

Akbari (2005) has shown that cleaning of some types of cool roof materials such as thermoplastic membranes can restore practically all of a product's initial reflectivity it is rarely practical or cost effective to do so. The benefits of cool roofs are clearly reduced by surface soiling. However, an analysis of all products in the CRRC database with an initial reflectivity of 0.70 or greater (average: 0.82), and an initial emissivity of 0.75 or greater, showed the average 3 year aged reflectivity of these products to be 0.70, with over 90% of the products having an aged reflectivity greater than 0.60. Most modeling on the energy and UHI mitigation impacts of cool roofs is based on an assumed value of 0.55 for aged reflectivity.

Some have postulated that in cold climates cool roof surfaces do not heat up as much as darker materials in the winter months, thereby making them more prone to condensation, and less capable of drying out any condensate that may form. Fenner (2014) reported on a survey of twenty four retail stores in northern US states. All the roofs had mechanically fastened reflective thermoplastic membranes and had been in place more than 10 years. None of the roofs had a vapor retarder. No evidence of condensation was found in any of the roofs. As the Department of Energy (2010) has noted with regards to the potential for condensation in cold climates, "…while this issue has been observed in both cool and dark roofs in cold climates, the authors are not aware of any data that clearly demonstrates a higher occurrence in cool roofs.."

Energy codes are calling for ever greater amounts of thermal insulation in buildings, which some believe negate the energy savings benefits of cool roofs Desjarlais (2012) ran simulations using the "Simplified Thermal Analysis of Roofs" (STAR) model to attempt to answer this question. They modeled a cool white roof, incorporating code mandated insulation levels, for a representative city in each of the USA climate zones to establish the base lines. They then repeated the analysis with a black roof, and found that additional insulation was required in all cases for the black roof to achieve the equivalent energy performance as the white roof (Table 3). Ramamurthy (2015) conducted a field study of 5 roofs with various combinations of albedo and insulation values (up to R48). They found that the most energy efficient roof construction consists of a high albedo membrane over high amounts of insulation at their location in the North Eastern USA, where the number of heating degree days is approximately five times greater than the number of cooling degree days.

Table 3: Additional insulation required for a black roof to achieve the equivalent energy performance as a cool roof

Climate Zone	Representative City	Default R-Value, White Roof,	Additional R Value required for Black roof
1	Miami, FL	20	17
2	Austin, TX	25	16
3	Atlanta, GA	25	11
4	Baltimore, MD	30	10
5	Chicago, IL	30	6
6	Minneapolis, MN	30	5
7	Fargo, ND	35	5
8	Fairbanks, AK	35	3

3.1.3 Cool options for steep-slope roofs

The most commonly used steep slope materials in the USA include asphalt shingles, various types of tiles, wood shakes and metals (which can also be used in some low slope applications). Traditionally, with the exception of white colored products, these materials had modest levels of reflectivity, typically 20 percent or less. There has been, particularly in the residential sector, resistance to the use of white products for aesthetic reasons. However, there have been significant developments in most technologies such as reflective granules in shingles, and advances in cool pigments for use on metal, concrete and clay tiles, to name but a few. A variety of "cool colors" is now available in most technologies, which removes a significant obstacle to broad implementation of the concept in sloped, particularly residential, market segments. Some steep sloped materials are approaching reflectivity levels of some of the more common low slope products.

3.1.4 Advances in Cool Roofing Technology

Developmental work is being carried out in most roofing material technologies to further improve upon the reflective properties of materials. Although still in the early stages, the use of fluorescent cool dark pigments is expected to provide metal roof coatings with unprecedented levels of reflectivity. Similarly, the use of synthetic granules will improve the reflective properties of shingles and modified bitumen membranes. One area of great interest is reducing the degree of soiling so as to maintain higher levels of reflectivity over time. Some suppliers are adopting photocatalytic technologies which trap and remove ground level ozone precursors from the air. In the longer term, shingle type products incorporating "directional reflectivity", will have a dark, traditional appearance from the ground, while the portion of the product's surface facing the sky will be reflective. Promising research is also being carried on thermochromic and electrochromic materials, that will shift color as temperatures change, potentially eliminating any winter heating penalty.

4. Reflective Surfaces in Policy

Cities and other jurisdictions have enacted a variety of programs and policies to encourage the deployment of cool roofs. Voluntary programs include awareness programs, volunteer cool coating initiatives, and incentive programs to reduce first costs. The most effective measures to drive a transition to reflective roofing have been cool roof requirements. In nearly all cases, the requirements apply to new roofs and when a roof is undergoing a substantial repair or replacement and include alternative compliance options such as solar PV installations or vegetated roofing. Chicago was the first U.S. city to require cool or vegetated roofs, in 2001. Since then, about half of the 30 largest cities in the U.S. have some sort of reflectivity requirement for roofs. Figure 3 details the evolution of cool roof requirements in the U.S.

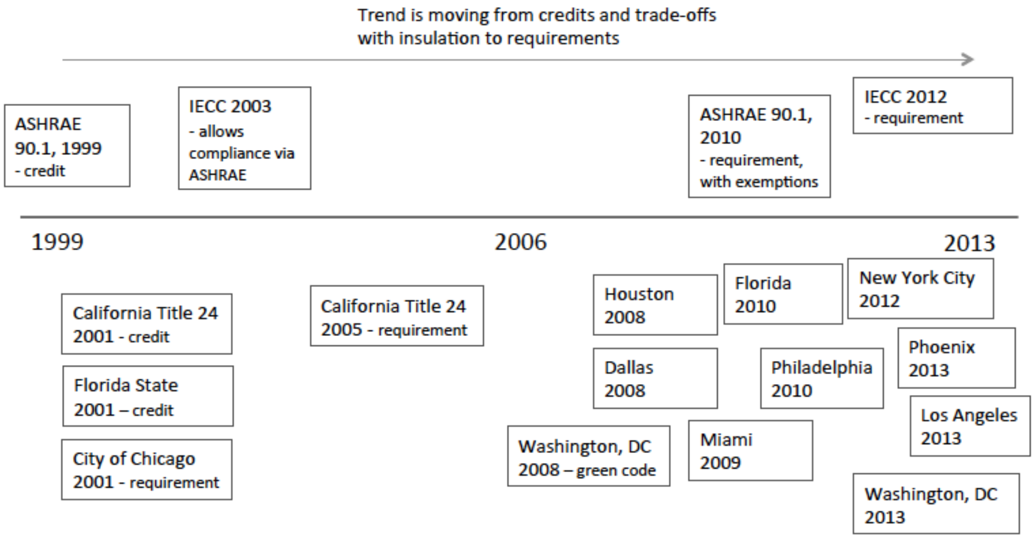

Figure 3: Evolution of cool roof requirements in the U.S.

5. Conclusions

The high concentration of dark heat absorbing roofs and paved surfaces covering significant portions of cities creates Urban Heat Islands (UHI), where localized ambient temperatures are significantly higher than in adjacent rural areas. These elevated temperatures contribute to reductions in air quality and decreased cooling energy demand in conditioned facilities. The additional GHG emissions resulting from the additional power generation compound the air quality issues. The confluence of climate change and the rapid urbanization projected over the coming decades will only exacerbate the problem globally. Broad adoption of cool roofing can play a significant role in mitigating these effects. By reflecting incident solar energy away from roof surfaces, they can moderate the UHI effect and decrease cooling energy consumption, resulting in a significant reduction in GHGs. Cool roofing can also reduce the impact of extreme heat events on occupants of non-conditioned spaces. Cool roofs provide the greatest benefit during peak power demand periods, which can delay or even negate the need to construct the additional power plants in many locations. All of these benefits can be achieved without appreciably changing the way we construct our buildings, and generally without a cost premium over traditional darker materials in all types of low and steep slope roofing technologies. Although a rapid transition to broad implementation of cool roofing strategies would be preferable, requirements mandating the use of cool roof materials in all new construction and during the re-roofing of existing structures will achieve the desired effect over time without additional cost to any stakeholder.

Green Roof Thermal Performance in Colombia

Sebastian Cardenas
(email: sa.cardenas420@uniandes.edu.co)

Hernando Vargas
(email: hvargas@uniandes.edu.co)

Abstract

In some European countries, green roofs have been a research topic stimulating a wide use of these applications. In Colombia, there has been a growing interest in the topic during the last years. The draft Agreement 386 of 2009 made by Bogota's City Council *"By which they are implemented, promoted and encouraged the development of green roof technologies in Bogota"* presented how green roofs and walls can contribute to improve the current environmental problems. Like other cities around the world, Bogota has flooding problems, loss of biodiversity, pollution, inefficient energy use and heat island effect, among others.

This study seeks to examine temperature regulation on a building's rooftop in the city of Bogota, Colombia; due to the influence of a green roof. Locally, there has been no research involving temperature measurements to quantify these effects. Thus, this investigation evaluate the effect generated by the green roof over the surface rooftop under exterior high and low temperatures. Additionally, the study sought to identify possible impacts of green roofing on the waterproofing membrane longevity, due to temperature fluctuations. This document discusses methodology used for temperature measuring along with analyzed scenarios during a four months measurement period. Results suggest that heat flux and thermal performance differences between the green roof and gravel ballasted roofs seem to be influenced mainly by solar radiation, ambient air temperature and volumetric moisture from the substrate. A deeper growing medium or increase on irrigation supply, may allowed the use of larger plants with potentially larger LAI which could reduce canopy air temperatures. This could lead to higher rates of evapotranspiration, and thus a better temperature regulation and further reduce heat flux into the building. Finally, conclusions are proposed about green roof thermal performance in a subtropical highland climate, and its isolation effect on decks or terraces.

Keywords: Thermal performance, green roof, insulation, sustainability.

1. Introduction

Natural cooling techniques in structures or buildings have been used through centuries. In recent decades however its use has been scarce due to the inclusion of air conditioning. The introduction of mechanical systems of air conditioning in buildings with its great energy consumption, has become the standard alternative for refrigeration and air conditioning of interior spaces in buildings today. According to Del Barrio (1998), green roofs do not act as a cooling mechanism, but rather as an isolation one by reducing heat flow through a building roof. It has been found that a well-designed and managed green roof can behave as a device of high quality insulation during summer in temperate zones.

Based on the study carried out by Ascione, Bianco, Rossi, Turni and Vanoli (2013) the following three aspects resume the physical phenomenon occurring during the operation of a green roof:

- Use of the inertial mass of the substrate such as a heat storage.
- Vital processes of vegetation such as photosynthesis absorb heat energy.
- The layers of soil and vegetation may induce ceiling cooling by evapotranspiration.

In addition, these physical and thermal behaviors of green roofs contribute to reduce the heat island effect, as the increase of the temperature in urban areas in relation to surrounding area. Akbari and Konopacki (2005) state that in large cities, this difference can exceed 5°C, since urban areas have extensive hard surface areas that absorb solar radiation and reflect the heat back into the atmosphere. On the other hand, in Teemsuk and Mander (2009) investigation, green roofs help protect roofs from extreme fluctuations of temperature, increasing the structural durability.

During the last decades, due to climate change and especially to the urban heat island effect; generated by continuous removal of green areas, green roofs have proved to be a cost effective alternative due to their ecological characteristics and its contribution to energy conservation in the construction sector. Besides, the application of bioclimatic concepts in the urban sector is limited by the fact that the densely built environment does not allow the use of vertical surfaces for passive solar strategies. Even natural ventilation, the simplest technique, is not always applicable since air and noise pollution in the urban environment lead to the need for airtight buildings. Theodosiou (2003) claims that horizontal surfaces of buildings, such as the ceilings or roofs, receive a high thermal stress during the summer and require strong measures to prevent excessive heat loss during the winter. Green roofs can be a solution to these problems.

1.1 Basic concepts

Çengel (2007) defines heat as the form of energy that can be transferred from a system to another as a result of a temperature difference. Heat transfer always occurs from the medium that has the higher temperature to the lower temperature, and stops when both reach the same temperature or equilibrium. Heat can be transferred in three different ways: conduction, convection and radiation. All modes require a temperature difference. The two principal ways of heat transfer in green roofs are explained next.

1.1.1 Conduction

Conduction is energy transfer obtained by the interactions between adjacent particles of a substance. It is a heat transfer process based on direct contact between bodies, where no exchange of matter occurs. The process can take place in solids liquids or gases. Experiments have shown that the ratio of heat transfer through a layer flat ($\dot{Q}$) is proportional to the temperature difference through this and the heat transfer area, but inversely proportional to the thickness of the layer, i.e.: $\dot{Q} = kA * \frac{T_1 - T_2}{\Delta x} = -kA * \frac{\Delta T}{\Delta x}\ [W]$

Doing the limit, where $\Delta x \rightarrow 0$, the above equation transforms to the differential form, which is called the Fourier law of heat conduction: $\dot{Q} = -kA * \frac{dT}{dx}\ [W]$

Where the constant of proportionality k is the thermal conductivity of the material, which is a measure of the ability of a material to conduct heat. A high value indicates that the material is a good conductor and a low value indicates that it is an insulating material or poor heat conductor.

1.1.2 Convection

Convection is the energy transfer mode between a solid surface and adjacent liquid or gas that are moving and includes the combined effects of conduction and fluid movement. Despite the complexity of this phenomenon, the transfer speed by this mode is proportional to the temperature difference and is expressed in convenient form by Newton's Cooling Law as:

$$Q_{convection} = hA_S(T_S - T_\infty)\ [W]$$

Where h is the convection heat transfer coefficient, in [W/m2*°C], A_S is the surface area through which heat transfer takes place by convection, T_S is the surface temperature and T_∞ is sufficiently away from the surface temperature.

2. Methodology

This study has been developed to fulfill three objectives: (1) Designing a controlled field experiment to compare thermal performance of green roofs on buildings; (2) Evaluate thermal-insulation effect of green roofs along a vertical temperature profile extending from outdoor air to green roof layers and to the ceiling surface and air; (3) Compare thermal performance of two plant species with different growing mediums. Prior to experiment design, literature review was made of journal published studies investigating green roof thermal performance by experimental measurements. This study is mainly based on the articles by Ascione, Bianco, Rossi, Turni, and Vanoli (2013); Parizotto and Lamberts (2011); D'Orazio, Di Perna, and Di Giuseppe (2012); Hien Wong, Chen, Leng Ong, and Sia (2003); and Getter, Rowe, Andresen, and Wichman

(2011), where parameters such as temperature, airflow, heat, and humidity were measure, in order to calibrate a mathematical model and perform simulations of different scenarios.

2.1 Site and green roof description

The site where the instrumentation was carried out to measure the temperature continuously in different layers of the green roof, was the central cafeteria inside the main campus of the Universidad de Los Andes. The roof is located in the South-East of the city of Bogotá on the lower part of the Hill of Monserrate, at latitude 4°36'02. 5"N, and longitude 74°03'54.8"W. The area has a climate with 11.5°C average temperature (maximum temperature of 23°C and minimum of 8°C) and 698 mm annual average rainfall, with a bi-modal distribution defined, from April to July and from October to December (IDEAM, 2014). This point was selected, due to the logistical advantages offered, and allowed to install an 110V electrical outlet for the data acquisition equipment. As well as having two different species of plants (Sedum and ferns) the green roof has an area of gravel large enough to have a control as shown in Figure 1.

Figure 1. Universidad de los Andes Green-roof

2.2 Equipment description

Temperature measurements were performed using 8 thermocouples type J, made with an iron and constantan wire. Thermocouples are the most common industrially used temperature sensor. A thermocouple is made with two wires of different materials together in one end, which when applying temperature at the junction of metals generates a very small voltage (Seebeck effect) of the order of millivolts which increases with temperature.

The equipment responsible for carrying out the conversion of millivolt thermocouple temperature measuring is a datalogger, which also allows to store the measured data. The dependency between the voltage delivered by the thermocouple and the temperature is not linear, therefore it is the duty of the electronic instrument designed to show the reading (datalogger), perform the linearization; i.e., take the voltage and knowing the type of thermocouple, see internal tables and match the temperature with the corresponding voltage, as shown in Figure 2.

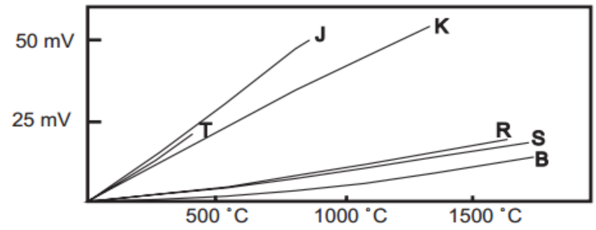

Figure 2. Temperature curve calibration for different types of thermocouples

The datalogger chosen for this research is the OMEGA model OM-USB-5201, which provide eight differential thermocouple input channels and have two integrated cold junction compensation (CJC) sensors for thermocouple measurements. Thermocouples inputs are software programmable for types J, K, T, E, R, S, B and N. An open thermocouple detection feature lets you detect a broken thermocouple. Also an on-board microprocessor automatically linearizes thermocouple measurement data. Finally the OM-USB-5201 has data logging capability, so measurements can be logged to a standard CompactFlash memory card (512 MB). These features allow all parameters to be measured and recorded at 5 min interval.

2.3 Measurement period

Temperature measurements began from late August until the first days of December of the year 2014. During this period of time three experimental stages took place. The first consisted in carrying out preliminary tests on experimental green roof trays arranged in the building of the Department of Physics and Geosciences of the Universidad de los Andes, where various green roof modules were implemented and instrumented in a previous research by Pérez and Groncol S.A. (2013). In these modules in different trays and at different media depths, temperature was measured during a period of time approximately 1 month, starting on 26 August and ending September 23. This first stage main purpose was to familiarize with the equipment and perform preliminary analysis of the thermal performance of green roofs. The second stage consisted of measurements in the ferns on the green roof of the central cafeteria at 4 different depths (Fig. 3); both on the part of the plant cover as well as in gravel cover. At this stage measurements took place for more than 1 month, beginning on September 29 and ending on November 7. Finally, the third stage as well as the second, consisted of measurements both in the part of the vegetation and gravel surface. However at this stage we measured on a Sedum portion of the green roof for approximately 1 month, beginning November 7 and ending on 2 December of the year 2014. Figure 3, shows the sectional drawing of Ferns and Sedum plants in the green roof. The gravel portion has the same distribution of thermocouples, the only difference is that there is no vegetation cover and instead of substrate or media there is gravel ballast.

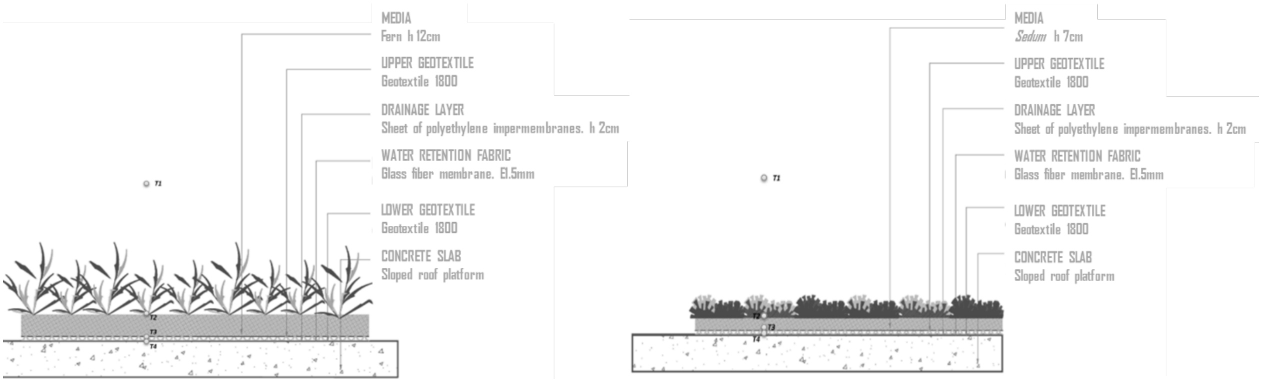

Figure 3. Location of thermocouples on green roof (Ferns and Sedum)

3. Results

Table 1, shows the conventions and location of the thermocouples placed on the plant species Sedum and ferns in the green roof and gravel ballasted roof.

Table 1. Conventions and location of the thermocouples in the green roof and gravel ballast

	Thermocouple	Datalogger Channel	Location
Green Roof (Ferns and *Sedum*)	1 *(T1)*	CH0	Temp. 1m height
	2 *(T2)*	CH1	Plant surface (Ferns and Sedum)
	3 *(T3)*	CH2	Beneath media or substrate
	4 *(T4)*	CH3	Water retention roof membrane surface
Gravel Ballasted Roof	5	CH4	Water retention roof membrane surface
	6	CH5	Beneath gravel
	7	CH6	Gravel surface
	8	CH7	Temp. 1m height

3.1 Ferns

Figure 4 shows temperature measurements results in the Ferns of the green roof at 4 different depths, always comparing with the control temperature of the gravel ballast. It can be observed that the day where the maximum recorded temperature arose was on 12 October, whilst the day where the minimum recorded temperature appeared was on September 30. Below are the results at the 4 different depths, where the first graph shows that the ambient air temperature is the same measure from 1m height of the ferns and the gravel, this fact confirms the validity of the measurements, and allows to analyze the rest of the data collected and draw conclusions on the thermal performance of a green roof.

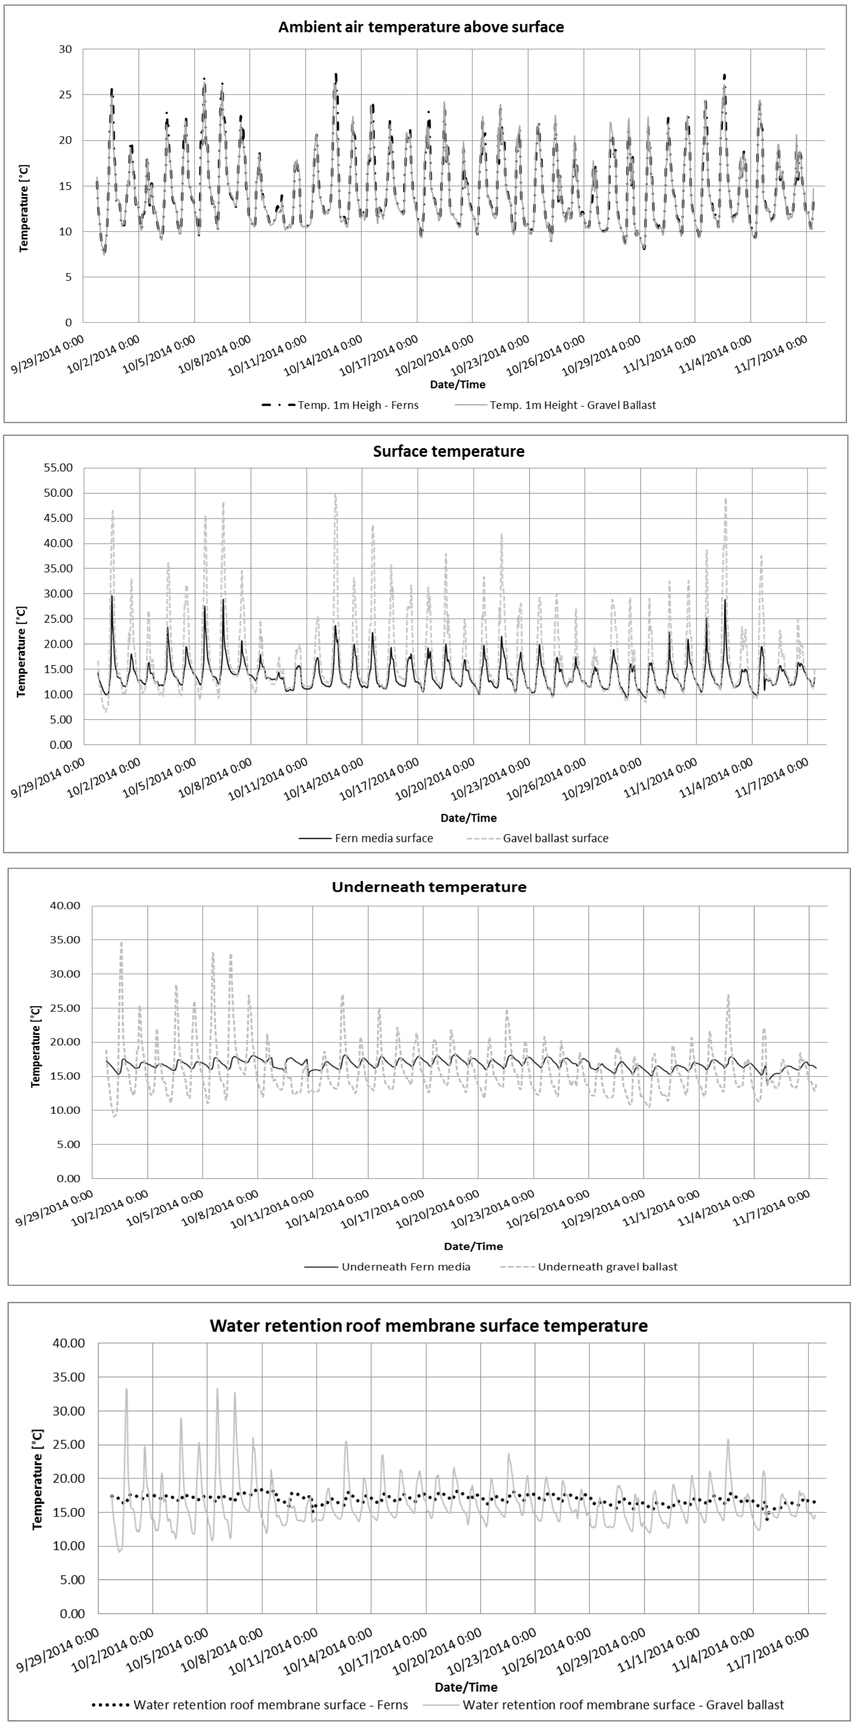

Figure 4. Ferns temperature measurements at 4 different depths

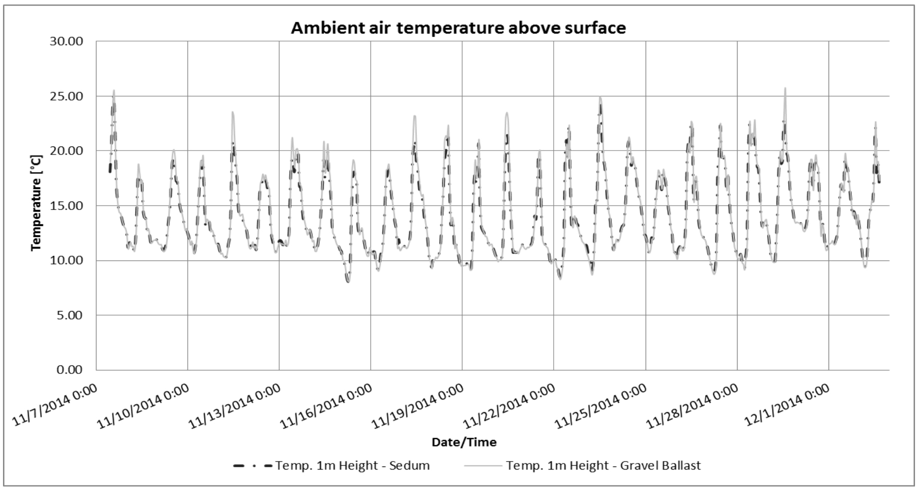
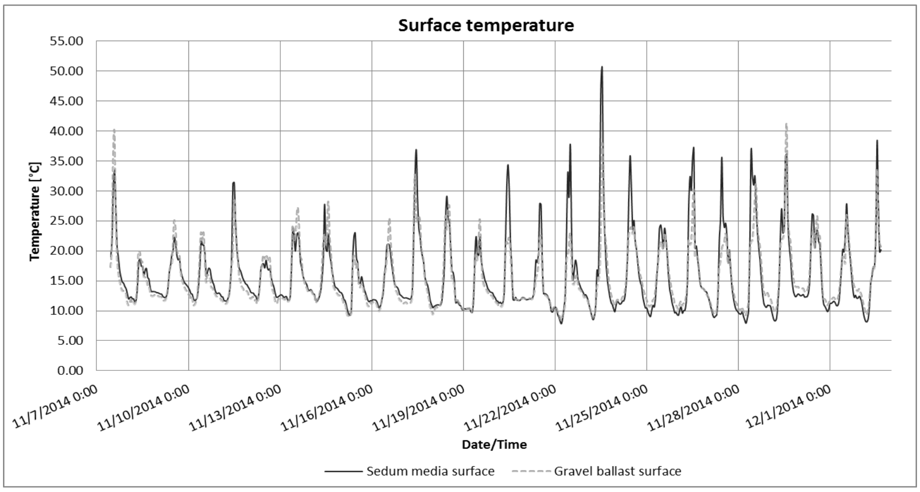
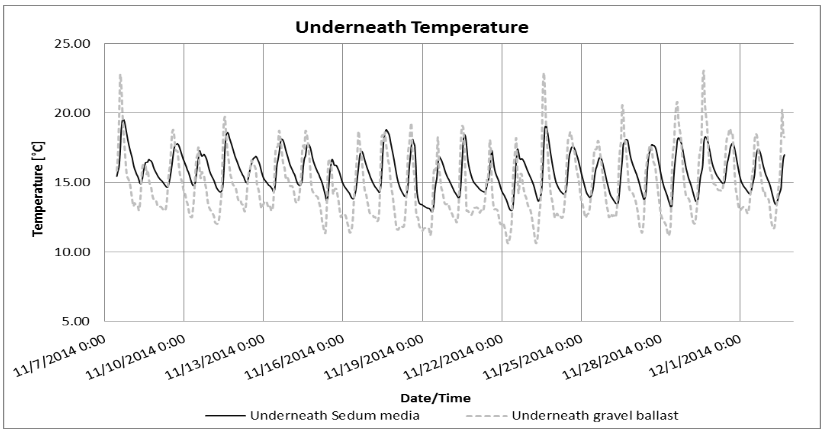
As expected, this maximum temperature was recorded on the surface of the gravel (Ch6), which in theory should gain much more heat than the surface of the substrate or growing medium due to shading from plant canopy and transpiration cooling provided by the plants. This phenomenon leaves a transcendental factor in evidence, and is the important potential function that complies the foliage of the plants against temperature regulation and therefor heat transfer to a roof ceiling.

3.2 Sedum

Figure 5 shows temperature measurements results of the Sedum at the same 4 different depths as the ferns. In this case, the day where the maximum recorded temperature arose was November 23, whilst the day where arose the minimum recorded temperature was 28 November. Following are the results at the 4 different depths mentioned above.







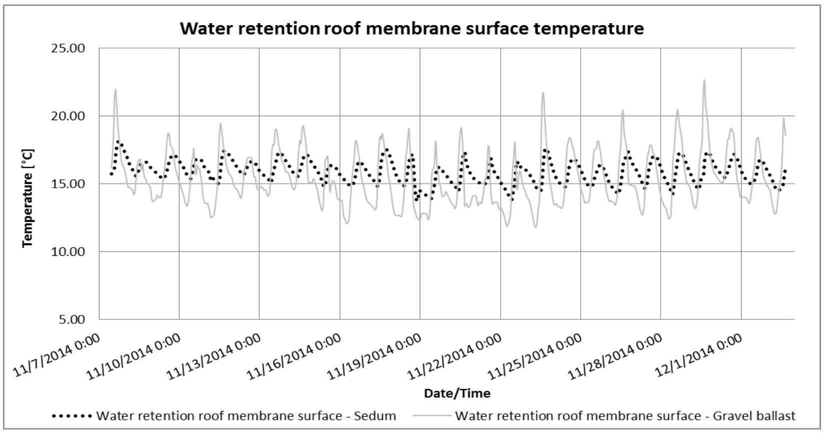


Figure 5. Sedum temperature measurements at 4 different depths

Unlike measurements in the ferns and contrary to what was expected, the maximum temperature was registered on the surface of the growing medium beneath the plants (Ch1) rather than in the surface of the gravel (Ch6). In this case the Sedum has less plant canopy (LAI) compared to ferns. This generates less shade and therefore heats up much more the substrate surface than the gravel ballast.

3.3 Heat transfer

In addition to the results of the measurements of temperature shown above, it was estimated the flow of heat that is transferred to the concrete slab both by gravel and green roof with ferns and Sedum. For this calculation we used the Fourier law of heat conduction explained above in the theoretical framework. Although heat transfer occurs by the combined effect of convection and conduction, in the next analysis we only took into account the conduction effect.

To calculate heat transferred from the surface of the gravel and green roof to the concrete slab, it was necessary to consult the literature for theoretical values of thermal conductivity (k) of gravel and a typical green roof substrate. For the green roof the study of Sailor, Hutchinson, and Bokovoy (2008), establishes that thermal conductivity of a substrate varies depending on its humidity, where k is between 0.25-0.34 W/(m*K) for dry samples, and between 0.31-0.62 W/(m*K) for wet samples. The adopted value of k for the substrate was 0.41 W/(m*K), based in the research by Becker and Wang (2011) where they used this value and also turns out to be a critical value, since corresponds to a humidity of 82% of the substrate. On the other hand, the thermal conductivity value adopted for the gravel ballast was 0.27 W/(m*K), since this corresponds to the value of k for dry sand according to the ASHRAE (1967), and was also used on Becker and Wang (2011) research. The depth of the fern substrate is 12cm and the Sedum growing medium is 7cm, whilst the gravel ballast is 5cm thick.

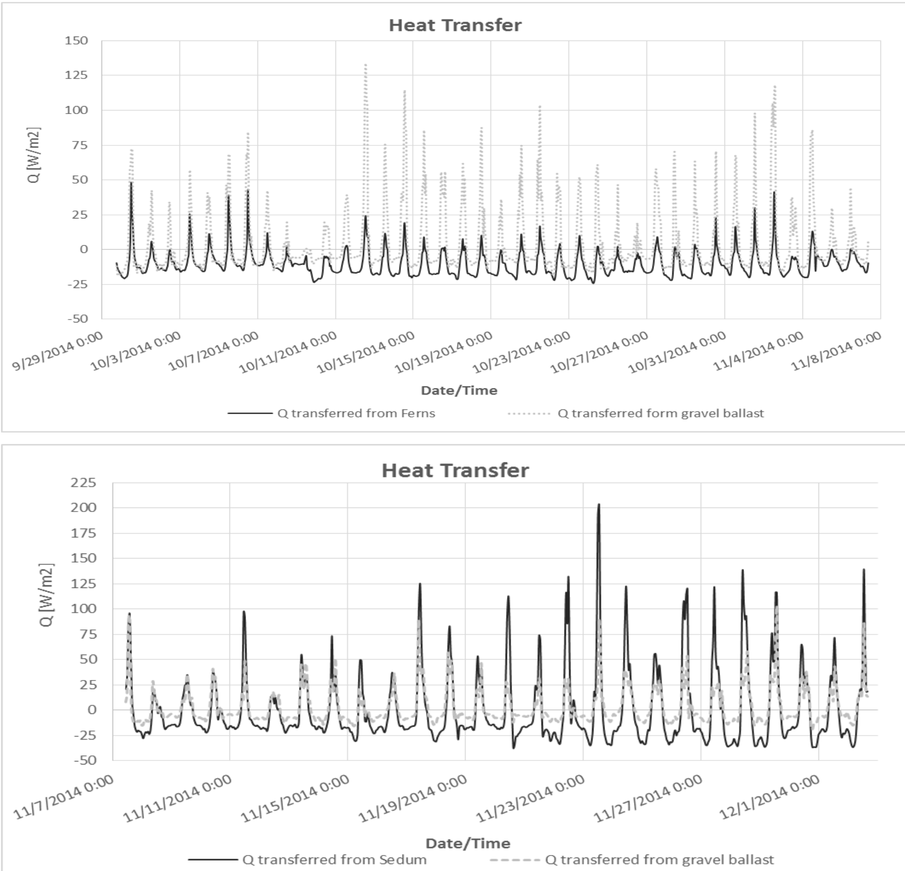

Figure 6. Heat transfer by conduction in Ferns and Sedum

Figure 6 shows heat transfer in ferns is much lower than in the Sedum. Heat negative values indicate that the flow is leaving the building, i.e., the building is losing heat. While positive values of Q indicate that the flow is entering the building, i.e. the building is gaining heat. Calculating heat flow allows to see the way in which heat travels through the green roof and gravel ballasted roof over time. This is useful to understand if green roofs have a better thermal performance than a control ceiling (gravel). However, values of heat alone do not express the overall thermal performance of green roof in comparison to gravel. To quantify the amount of heat that the green roof prevents or avoids the building loses in cold weather and win in warm weather, heat flow values were converted into gained or lost energy per square meter of roof. Heat flows are in W/m^2, therefore to convert them to an amount of energy transferred, heat flow must be multiplied by the period of measurement in seconds.

$$\frac{Energy\ Gain\ or\ Lost}{m^2}[MJ/m^2] = Q_m * t_m$$

Where, Q_m is the average heat flux in the period of measurement, and t_m is the number of seconds in the period of measurement.

4. Discussion

During the second experimental stage, Ferns portion of the green roof lost in average 34.09 MJ per square meter. This means that on average the effect of the green roof implementation with ferns prevents the structure to gain heat or produce an upward heat flux from the concrete slab toward the surface of the substrate. On the other hand, throughout the third experimental stage, both Sedum and gravel gain heat. Sedum gain in average 0.35 MJ of energy per square meter. Hence on average the effect of the implementation of the green roof with Sedum prevents the building gaining 6.04 MJ/m^2, due to the roof portion with gravel gain in average 6.39 MJ/m^2. In both experimental stages, the portion of control roof (gravel) gain more energy than the one with green roof (Ferns and Sedum). This let us conclude that on average the effect of having no vegetation cover in the portion of gravel produces the building roof to win heat or gets hotter through a downward heat flux from the gravel surface onto the concrete slab. A deeper growing medium like in the Ferns substrate, allowed larger plants with potentially larger LAI to grow, which could reduce canopy air temperatures and further reduce the heat flux into the building.

5. Conclusions

Results demonstrate how roof temperatures and heat flux are influenced by a green roof in Bogotá, Colombia during a period of time of almost 6 months. The investigation is worthy because most research focus on green roof thermal performance in seasonal places or with temperate climate, but Bogotá has a very steady weather over all the year without no seasons. In the case of this study heat flow was calculated only by conduction for each stage of measurement which must be very close to the total transferred energy flow in a conventional roof. A more complex model that also considers the transfer of heat by convection and radiation would be needed to quantify and understand the total flow that moves through the substrate and vegetation cover to the concrete slab. For this reason, convection and radiation heat flows were not considered, and also the equipment used only allowed to measure the transfer of heat by conduction.

In terms of obtained results, it can be concluded that with the shade generated by plant canopy, the temperatures measured on the surface of the substrate, for the two types of vegetation were lower than measurements on the surface of the gravel ballast. The maximum decrease in temperature caused by the plants was around 25°C. The temperature measured under the vegetation varied according to the LAI of the plants. Heat transfer through the control roof (gravel) was greater than through the green roof. Thermal benefits generated by the green roof were the combined effects of the depth of the layer of substrate and vegetation. The damp medium can provide an effect of additional insulation on the roof during all day, whilst vegetation mainly provides protection against solar radiation.

Abstract

Airtightness and control of the internal ventilation are among the main factors to be considered in order to evaluate the energy efficiency of a building; moreover, they both strongly influence indoor air quality. Building airtightness has several advantages, such as the reduction of uncontrolled passage of cold draughts and of interstitial condensation. Non-adequate building envelope airtightness can cause mould formation. Some moulds are not infectious, while others produce toxic substances called "mycotoxins" that cause serious infections in more vulnerable people. Other types, such as Cryptococcus, may instead endanger everyone's health. The sick building syndrome is one of the unpleasant consequences of uncontrolled air draughts, which contribute to the distribution of spores within the environment. Therefore, in order to verify the energy and environmental performance of the building related to airtightness, the "Blower Door Test" is used to measure the hourly rate of air exchange caused by the inaccurate installation of doors and windows, to the presence of passing pipelines or to common construction defects. The test is carried on closing all the openings and placing a fan as temporary replacement of a door. The test, carried on with the aid of a thermal imaging camera to identify the critical points and optimize the airtightness, gives general information about the construction quality. The paper presents the testing method and the results of air permeability "Blower Door Test – Method A", carried out on March 6th, 2015 at a private residence located in Fiume Veneto, PN, Italy. The test verified that the value fell within the limits for the building certification according to the CasaClima A Protocol. The paper wants to highlight how an appropriate level of building airtightness, together with a mechanical ventilation system, allows reducing heat losses but also contributes to improve the quality of indoor air with the reduction of pathologies for users.

Keywords: Blower Door Test, airtightness, Indoor Air Quality, mechanical ventilation, Sick Building Syndrome

1. Introduction

Airtightness is one of the most relevant features to optimize the technical performance of the building envelope. Proper design and construction of air-tightness of the envelope ensures:

- The reduction of energy losses for ventilation;
- The reduction of energy requirements;
- The thermal protection of the envelope, in order to avoid sudden changes in temperature;
- The absence of passage of sound in an uncontrolled way;
- The reduction of any external or internal pollutants, due to the masonry (formaldehyde, radon, pentane, etc.);
- The absence of uncontrolled air currents;
- The correct functionality of the ventilation system;
- The absence of interstitial condensation and the consequent deterioration of the structures or the growth of hidden mould or brown rot.

PassiveHaus Institute indicates that in the presence of a slot of 1 mm and 1 meter in length, the formation of a mould amounts to 360 g of average water per day in presence of an internal temperature of 20° C and 50% of Relative Humidity (RH) with 0° C outside and 80% of RH. The mould mechanism is well explained in an article of WBDG – National Institute of Building Sciences USA (Morse, Acker 2014) and correlated with the absence of air tightness (*exfiltration)*. Condensation triggers the formation of fungi in wood buildings: one of the most important brown rot fungi is Basidiomycota (Palanti) that, according to the National Institute of Health (Mondello 2008), can cause cryptococcosis, pulmonary mycosis that may occur in patients already immunocompromised. During summer, as also indicated in Morse, Acker, the same mechanism in the opposite direction causes the entrance into the room of the spores (*infiltration)*. As the pollutants from the inside of the wall can enter in the internal environment, in the same way the interior pollutants can stop in uncontrolled cracks proliferating in the presence of mould and determining the possibility of concentration of further biological mass. In buildings where the tightness is improved, certified with blower door test, and in presence of a mechanical ventilation system, users are positively affected by better environmental conditions (Voci 2014).

The "blower door test" evaluates the airtightness of a building. The method determines the hourly rate of air exchange caused by gaps in the building envelope, due to the inaccurate installation of doors and windows or to the presence of cables and pipelines passing gas, or general construction defects. The test is performed closing all the openings to the outside, including air inlets on the walls of the kitchen, and powering a fan placed in temporary replacement of a window or of a door which lowers and raises the pressure within the interior volume; instruments that measure the pressure difference between inside and outside and the intensity of the air flow are connected to the fan. The measurement is corrected considering the atmospheric pressure, the temperature outside and inside of the building and the wind speed. The test is performed with the aid of a thermal imaging camera to better identify the critical points and optimize the airtightness. The test gives a global measure of the building quality construction, allowing to avoid problems such as: interstitial condensation with consequent degradation of building components, unbalance of mechanical ventilation, increase in energy consumption, uncontrolled passage of noise, uncontrolled passage of pollutants from the outside, etc.

The “blower door test” can be carried out according to two methods defined in UNI EN 13829:2002 – “Thermal performance of buildings – Determination of air permeability of buildings – fan pressurization method”, (the current EN at the time of the test, now substituted by ISO 9972:2015): Method “A”, which can be made only when all finishes are complete, including the installation of sanitary, and Method “B”, which can also be carried out in unfinished buildings, with the doors and windows already installed, for early detection of possible losses of the airtightness. It is suggested to use the method “B” at the time of installation of windows and systems already installed, in order to control the structure-frame nodes, the plants passages and more generally any node of connection between different parts of envelope. Since the case study building of this paper was already finished, the Method “A” was used.

2. Description of the building and of the refurbishment

A compact volume characterizes the building, with the main front almost exactly facing south. It is part of a complex of terraced houses in Fiume Veneto, in the province of Pordenone, in a district built in the seventies.

Figure 1: South elevation of the building

The property already made some changes to the building, with the installation of photovoltaic panels and the replacement of the old gas boiler with a condensing one. However, these interventions, despite having brought a reduction in expenses for electricity and a slight reduction of costs for heating and domestic hot water, had not yet solved the constant and repeated mould growth on interior surfaces. The target of the project were therefore:

- make rooms permanently healthy, both through the control of thermal bridges to prevent the formation of mould, both by the application of new painting in low VOC emissions;
- a great reduction in energy demand, achieved through interventions on the entire building envelope (insulation, replacement of windows and mechanical ventilation with heat recovery on time) and on the plant.

Due to the constraints of the building (PV system already installed, the presence of thermal bridges, permanence of users during works and presence of adjacent buildings), it was decided to combine exterior insulation with a limited internal insulation. Particular attention also has been taken to the proper execution of tightness, both on the perimeter of windows, both closing with sponges to tightness the existing corrugated pipes. The application of the thermal insulation on the outside of the building has brought benefits both in winter and summer; Furthermore, the presence of a staircase for access to the roof allowed to take advantage, during the summer months, of the chimney effect, optimizing the intervention for the typical hot and humid climate of this geographical context.

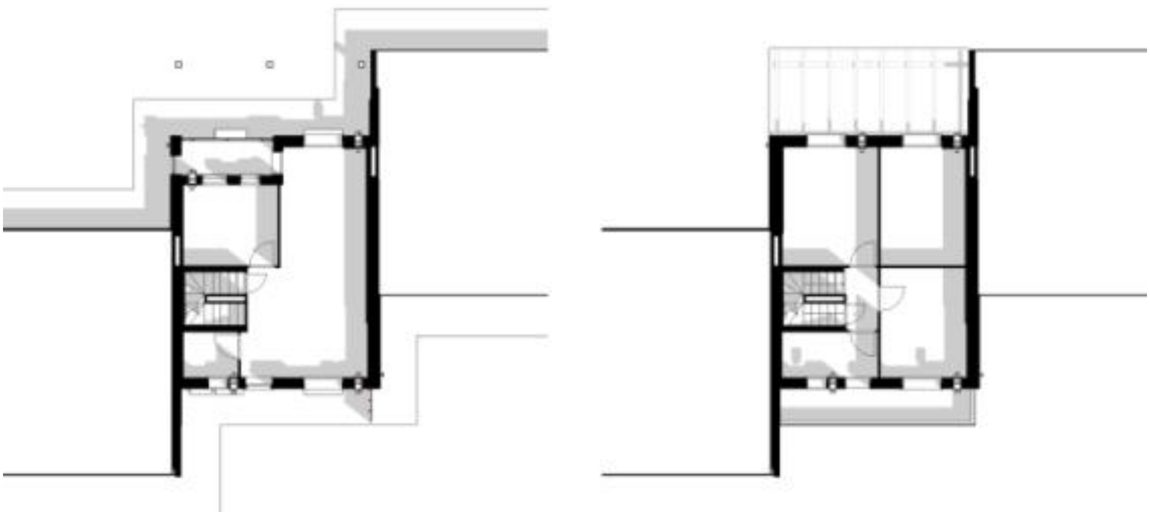

Figure 2: Plans of the ground floor and first floor

North and south façades, being free parts, were isolated with exterior insulation; east and west fronts were, where necessary, insulated inside. Roof was isolated with outside panels coupled with bitumen; over them, washed gravel plates, retrieved before the beginning of works, were then installed. Concerning the internal partition over the cellar, a layer of insulation coupled with plasterboard panels was positioned at the intrados. The thermal bridges caused by different solutions of thermal insulation (internal and external), were solved by extending the outer insulation beyond the limit of the heated volume. This is why the degraded existing external platforms were demolished, thus being able to continue the outer insulation of the walls to the ground and consequently solving the thermal bridge perimeter. Finally, doors windows provided with abutment to the ground were installed; this guarantees the correct installation of the perimeter and of new triple glazing window with PVC frame, coupled to new rolling shutters box designed to accommodate the thickness of thermal insulation. The works carried out have significantly improved the technical characteristics of the housing that reached the transmittance values given in Table 1.

Table 1: Data of the building elements transmittance after the intervention

Element	*Trasmittance value*
Wall	*0.15 W/m^2K*
Roof	*0.15 W/m^2K*
Floor	*0.49 W/m^2K*
Window frame (Uf)	*1.20 W/m^2K*
Window glass (Ug)	*0.70 W/m^2K*
Window total (Uw)	*1.02 W/m^2K*
S/V ratio	*0.82 m^{-1}*
Average trasmittance (Um)	*0.23 W/m^2K*

3. Description of the test

The test was carried out on March 6th, 2015. The instruments used, in accordance with UNI EN 13829:2002 – "Thermal performance of buildings – Determination of air permeability of buildings – fan pressurization method", were:

- The blower door test system, including air tightness sheet, adjustable fake aluminium frame to be fixed temporary to the door and the fan;
- The control gauge for the measurement of air changes inclusive of data cable, to be connected to the fan, USB cable for PC connection, coloured red pipe to be installed over the sheet outside the building for the control of external pressure, yellow pipe to be connected to the fan for the control of the pressure generated by the fan itself;
- A o-hygrometer to check the temperature and humidity of the air, inside and outside;
- A PC equipped with control software Retrotec FanTestic Pro;
- A camera;
- A thermal anemometer.

Table 2: Test equipment

Digital camera	*Casio Exilim*	*Resolution 20.1 MPix* *Optical zoom 6x*

To perform the blower door test according to Method "A" all finishes including toilet services must be installed; the building must then be ready to be inhabited. The preparation of the test were as follows: once calculated the net volume of the heated volume, the sheet was installed on a appropriate opening, usually an entrance door; in this case, the used blower door test system was suitable for openings from 74-112 cm to 134-247 cm. The frame jamb must be not less than 30 mm; in this case the test frame must be installed over the frame. The chosen opening should not be exposed to the sun to avoid system overheating and changes of pressure difference between inside and outside in a way not in accordance with the real climate data. For safety reasons, during the installing activities the site was adequately illuminated and provided with supply power, particularly few meters close to the opening used for the test. It is useful having a temperature difference between interiors and exterior so, when the depressurization starts, the incoming air from the slots is recognizable since it has different temperature compared to the surfaces and the indoor air. At the same time, to avoid uncontrolled convective motions and not dependent on the test is useful to not heat any heater or fireplace before the test and eliminate combustion ashes. In order to carry out the test, all openings to the outside (or to cellar, attic, garage, etc.) were closed and the interior doors were opened. In addition, concerning the corrugated tubes, both the interior space between the pipe and electric cable and the space between the tube and the building structure must be sealed. Sanitary discharges were filled with water during the test to prevent from depressurization pumping in smelly gases; furthermore, air hoses have been sealed to prevent the passage of air. During the test, it is strictly forbidden to open the doors between inside and outside, to prevent an uncontrolled speed growth of the fan, resulting in possible failure of the electric motor. Once installed the sheet and prepared the building for the test, the fan, the gauge and its connections to the PC were installed. The following data related to the envelope, essential for the calculation of the air exchange times, were then input into the software:

Table 3: Test data

Fan position	
External opening	*Entrance door*
Orientation	*South*
Altitude above sea level	*20m*
Altitude from the building ground	*0m*
Building data	
Net volume	*343m*^{3}
Envelope surface	*383m*^{2}
Net floor surface	*124m*^{2}
Wind speed	*1 – wind breath - 0.45÷1.34 m/s*
Temperatures and atmospheric pressure	
Inside	*21.5°C*
Outside	*14°C*
$\Delta\theta$	*7.5 K*
Atmospheric pressure verification	*OK - (UNI EN 13829)*

The test was carried out with the following conditions:

- the kitchen hood was sealed during the test;
- heat pumps were not sealed;
- all equipment for ventilation were sealed.

At the beginning of the test the fan was filled on the inner side with a sheet to verify the pressure difference with initial flow equal to zero, with the software set to a predetermined time interval. Once acquired pressure data with flow equal to zero, the membrane temporarily placed on the inner side of the fan was removed and the test according to the Method “A”, that plans to carry out the test first in depressurization and then in pressurization. At the end of the test, the fan on the inside was stopped to check again the pressure with flow equal to zero. The software was set to obtain 10 static pressures at flow equal to zero for 10 seconds each, both before each test (first to depressurization and subsequently for pressurization), both at the end.

11 pressure measurements of the building, first in depressurization and then in pressurization, were acquired, from 15 Pascal up to reach 65 Pascal, with increasing not greater than 10 Pascal. The software was set up to analyse each point of analysis for 20 seconds, for a total of about 4 minutes for each test, during which between 100 and 200 detections were carried out.

During the pressurization phase, in the ranges between -20 and -30 and between -50 and -65 Pascal pressure was not completely stable. This change is the result of the turbulence of the fan due to the conditions of the machine: in the specific case the corridor where the door opened was narrow compared to the needs of the fan. The values measured during the test in depressurization were mediated according to the pressure and, through the points thus identified, a regression line was identified. The points refer to the test in depressurization are well aligned to the regression line, with a correlation index of 99.59%.

The same test was also carried out in pressurization, identifying a number of sealing points useful to define the regression line for the pressurization phase. Placing in the same graph both the straight line representing the depressurization both the one referred to the pressurization, it can be noted that pressurization give values of exchange air time lower than the depressurization; moreover, there is a shorter distance with the high pressures than low ones.

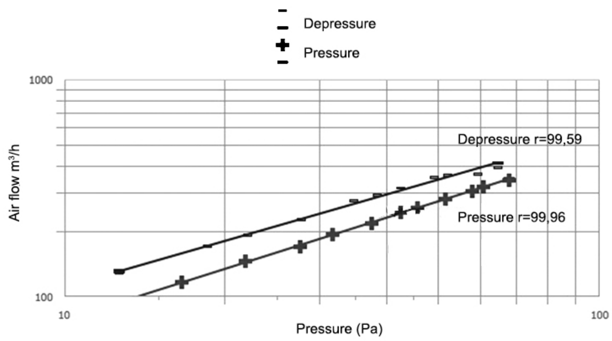

Figure 3: Comparison between pressurization and depressurization lines

In the overall results, during the depressurization air changes times 50 Pa, n50 [/ h] amounted to 1.007, while during the pressurization air changes times 50 Pa, n50 [/ h] amounted to 0.7997.

It is conceivable that air exchange values lower concerning the pressurization compared to the depressurization are dependent from the taping for the sealing air during pressurization, which is "pushed" toward their place, determining a greater efficiency in air tightness. On the contrary, during the depressurization the strips are pulled, facilitating the entry of air from outside. Once the test was finished, results have been obtained by mediating the values of pressurization and depressurization:

Table 4: Results

Air flow at 50Pa	*310.0 V50 [m³/h]*
Hourly air exchange at 50 Pa	*0.9035 n50[/h]*
Air permeability at 50 Pa	*0.809 q50[m³/h/m²]*
Specific flow infiltration at 50 Pa	*2.499 w50 [m³/h/m²]*

The value of tightness obtained was within the range of acceptability to obtain "CasaClima" label. This Protocol requires that buildings that consume less than 30 kWh/m^2 per year must present an air exchange lower than 1.0 h (-1) ± 0.1. The value obtained from the test was n50 = 0.9035 ± 10% h-1 and therefore results were within the limits.

The checking carried out during depressurization CRUISE mode also allowed to highlight some critical issues that, in part, have been corrected and that influenced the final result. Such criticalities have been identified using the thermal imaging camera evidencing the cold spots due to entry of air from outside. Among the most critical issues some electrical outlets were highlighted, affected by air leaks and where the sealing can be improved; the shutters of the windows, where not significant leakage occurs compared to the other but, anyway, present; and the vents, that, despite having been taped as required, presented air losses that affected the performance of air tightness.

4. Discussion

The works carried out in the building produced a significant improvement in performance sealing and envelope insulation. The blower door test has allowed us to identify any additional areas that need work, certifying also good airtightness of the refurbished envelope. The thermal imaging camera has highlighted as points of discontinuity in the envelope, such as window frames, electrical outlets or ventilation ducts, can be a weak point for air tightness. They therefore require an adequate design and checking, which can be carried out precisely by using the methodology presented in this paper. In particular, in addition to Method “A”, useful for buildings already finished, the blower door test Method “B” can be used to evaluate the correct installation and sealing of doors and plants.

The benefits from the refurbishment are not limited to the reduction of energy consumption. Actually, the absence of an adequate air tightness causes a uncontrolled passage of air that, in winter, contains a considerable amount of water vapour. This steam, during the migration towards the outside, touches the cold portion of the stratigraphy on which condensation may form. In wooden buildings and in buildings with traditional wooden roof this constant water storage determines an ideal environment for mould growth, including the brown rot. Among the main fungus brown rot is the Basidiomycota (Palanti) that, according to the National Institute of Health (Mondello, 2008), may cause Cryptococcus, a fungal lung infection that can occur in patients already immunocompromised. These same air currents that caused the formation of mould spores can carry spores inside, increasing the number of indoor pollutants (Horn, 2014), up to the limit beyond which could appear the presence of SBS (Sick Building Syndrome). In not historical masonry buildings, with the exception of the situations in which seismic phenomena have caused cracks in the walls, the most critical elements are the ventilation channels not adequately maintained where – like the ventilation systems of hospitals, although in a lower amount – may form over the years a layer of wet dirt that encourages the growth of bacteria. Similar phenomena may also occur in electrical corrugated channels that can serve as conduits for the passage of humid air (toward the outside in the winter and towards the inside in summer). However, while a cleaning operation with the steam ejected by a probe in ventilation ducts can be done, this is not possible in the electrical channels, which remain therefore a potential critical element. Finally, in “traditional” historical buildings (in masonry), where cracks of the masonry are evident, it is not possible to exclude the deposition of the powder through openings and the formation of interstitial condensation, with the consequent proliferation of moulds and bacteria.

In general, every interstice present in the building envelope may allow the formation of a microbial ecosystem (moulds or bacteria), similar to the one present in domestic dust (Barberan et al., 2015); this phenomenon increases when the airtightness of the building elements is not guaranteed, thus allowing an uncontrolled air flows which favour the transfer of the biological charges and the formation of condensation in the interstices. Also window frames must be included among building elements subject to these issues, since if they are not properly completed or installed, can facilitate the passage of air and the resulting accumulation of dust and dirt at the jamb and seals. These points are likely to the formation of condensation, given the position between inside and outside, becoming a privileged point for the formation of pathogens. Adequate airtightness of buildings is, therefore, an essential technical feature for the protection of healthy indoor air. In this way, it is possible to add a mechanical ventilation system, which allows also to control the exchange of air in indoor environments, allowing the elimination of volatile pollutants.

5. Conclusions

The refurbishment of the building shows how important is not only install renewable energies systems, but also provide the building itself with an adequate thermal insulation, and at the same time ensuring the airtightness of the possible passage points of air between inside and outside. A non-optimum airtightness, in fact, may lead to a worsening of the quality of indoor air, with the consequent diseases for the users. The use of the Blower Door Test allows the control of the airtightness of the housing and at the same time the use of the thermal imaging camera allows to check the presence of air passages through the building, thus allowing to intervene to improve the performance of the building.

VIA University College,
Centre of Applied Research & Development in Buildings, Energy & Environment
(email: hbl@via.dk)

Abstract

In Denmark we currently have an increased focus on preserving the most valuable domestic building examples from the period 1945 - 60. New literature deals with these architectural heritage matters. The authors of this paper argue, that due to question of preservation the buildings physiology is not enrolled in the discussion, and argue that especially this issue can cause a huge damage on the aesthetics of the architectural expression, the facades and the use of the buildings in terms of comfort demands for people living here.

The starting point for the research is preservation, comfort and aesthetics. The primary topic of the survey is the building envelope as a transmitter of external climate to internal climate and vice versa. Three case studies and one reference building as principal renovations are used as information for new innovative and integrative solutions. Analyses and discussions will show a development to the introduction of mechanical ventilation in the building stock with a particular focus on decentralized ventilation systems. To evaluate the retrofitting initiatives a cross-disciplinary corporation between the professions of architecture and engineering are required: this integrated working methodology develops new renovation processes.

Based on both quantitative measurements and on qualitative judgements the cases are analysed comparatively. Parameters such as ventilation solutions in facades are discussed as architectural consequence and value. User interviews will also inform the evaluation. Cases are chosen from earlier research projects and brought into the analysis in order to either see a development or to see more clearly how integrated evaluations of the ventilation and the preserving strategies can lead to a better understanding of an optimized intervention. The paper concludes that interdisciplinary ways of working will improve both architecture and preservation and comfort, and that higher value hereby is created. Furthermore the new initiatives from the industry are shown, which indicates a movement towards innovation of decentralized ventilation solutions.

Keywords: cross-disciplinary cooperation, indoor climate, decentralized ventilation, energy renovation solutions

1. Introduction

The Modern Movement in the 1920s was a reaction to the former stylistic architecture and to the urgent need for low income housing: several architects took the initiatives towards the Modern Movement (CIAM 1933).The modern architectural ideas were among many other ideas defined according to new construction possibilities and industrialized methods: new forms and proportions, flat roofs and no decoration, new materials such as reinforced concrete and steel. New rational building methodology was the new mantra for the movement. The housing areas were laid out in open parks and designed with better flats, where the functionality was the basic fundament for space, distribution and orientation, sun, light and air for people from the working class.

Danish progressive architects were inspired by these ideas and they designed new ways of living at the outskirts of the cities. After WWII there was scarcity of materials, and the modern ideas were moderated to the actual possibilities of solving a huge demand for dwellings. This situation created the modest functionalistic architecture (Nygaard1984), where architectural ideas were designed and built by Danish local craftsmanship, constructions and materials. The result was a special local translation (Lund1993) of these modern thoughts into a large number of very fine suburban areas characterized by masonry and very fine architectural design.

This paper will focus on the functionalistic housing built in the period after WWII 1945 – 1960 (Vestergaard 2011), which represents a most valuable treasure in the diverse Danish urban fabric, especially regarding functionality and aesthetical qualities. The period is known for its embedded qualities both in respect to architecture, space and daylight, but also paying respect to traditional materials and modernistic form and detailing.

Figure 1: Typical housing block, entrance, balconies

The buildings are of different value, but a considerable majority belongs to the architectural heritage of the period (Bech-Danielsen 2015). The buildings are characterised by red or yellow masonry and of high aesthetic quality. The facades are aesthetically well designed and the geometry includes important functional detailing such as very efficient ways of dealing with materials and proportions, balconies and details see figure 1. Basically the architecturally expression of these treasures must be kept through the future retrofitting. The building law is reflected by the designs which address demands to staircases, balconies, indoor design/organisation and size, but also address demands to fresh air and ventilation.

The airflow through the dwellings reflects the building practice of the time and the Copenhagen Construction Law (Københavns byggelov 1939) and was originally operated by separate natural air channels related to the bath and kitchen, see figure 2.

Figure 2: Natural ventilation distributed through facade related to kitchen and bath

Today's urgent demand for retrofitting is caused by the massive backlog in the housing sector, rising energy prices and fulfilling the European targets of CO2-reduction within 2020 and recently 2030 (EU 2010), which generates a growing demand for new renovation solutions for insulation and air-tightness of the existing climate screen.
By upgrading the climate screen and introducing balanced mechanical ventilation in a number of cases this paper will show, how the comfort in the dwellings is improved through the controlled indoor climate and how the air change has become a parameter to estimate indoor air quality. Balanced mechanical ventilation has been introduced to the existing brick buildings from the 1950s social housing, and development of innovative ventilation solutions have moved from centralized to more decentralize over the last decade (Klint 2009b).
This paper argues that there is a development in new ventilation solutions, towards more sensible solutions, while introducing the balanced mechanical ventilation to the buildings from before 1960. Considerations of where and how to place the ventilation unit will be carried out. Economical perspectives and development towards higher energy efficiency of units will be predicted. The challenge of securing a good indoor climate and a high user satisfaction will be argued. It is realized that very little Danish statistic references in terms of technical ventilation systems in existing multi-story housing, have been carried out. Whereas the statistical investigations have been done in Central Europe regarding office buildings (Mahler and Himmler 2008). However; it is here estimated, that mechanical extraction is the most commonly used ventilation system of today in the multi-story housing in Denmark.
When discussing renovation and architectural heritage, it is very important to establish a holistic understanding and framing. The aim of this paper is to review the complex problem in which the research focus is imbedded. To challenge the discussion it has been chosen to focus specifically on the climate screen as an instrument for better comfort in respect to light, sound, temperature, humidity, energy and air and not to forget preservation of the aesthetics of the architecture. In order to point out broader perspectives the complex challenge is done interdisciplinary.

The research question to explore: How to perform a cross-disciplinary cooperation in renovation of social housing to preserve the architectural expression and the facades and the use of the buildings in terms of indoor comfort?

2. Methodologies

The investigation is based on measurements and simulation from four cases, in which selected parameters within energy renovation has been documented, analyzed and evaluated through a triangular survey of quantity, quality and user experiences from questionnaires.
General and newly developed knowledge from the study of literature are brought into the discussion and compared to the case studies.
In order to open the research and discussion, we have used comparative analysis methodology. The reference and the three cases represents a development in Denmark from 1915 up to 1960, both as architectural and construction wise relatively broad change, but especially the demands to indoor climate and energy efficiency compared with the preservation question.
An integrated research process can be understood as a concept in which the determination and development of a product or a process integrates all relevant parameters, ranging from the aesthetical and the psychological aspects to the technical, the logistical and economical aspects. The authors of this paper have as a team developed the research as an integrated research process, which methodologically builds on tools such as 'Clean Process' (Blyt 2013).
Regarding the content of the research we have focused on architecture and engineering, on architectural heritage, on indoor comfort and on user demands: from this foundation the idea of the abstract has appeared. From the very beginning of this survey the broad discussion has played a driving role for defining the content, the analysis and the discussions of both the problem and the working methodology of the integrated research process.

In order to establish the current state of ventilation principles in existing multistory housing, the conditions are shown, see figure 3 for three different balanced mechanical ventilation approaches for renovated housing and for a reference case characterized by natural ventilation as a normal situation for housing built before 1939.

3. Criteria and Findings

The defined parameters for the survey are listed below. Data and sources are quantified and qualified, and user satisfaction is brought into the evaluation. Through the survey the value based importance of the parameters are found.

3.1 Architecture and preservation

It is evident that many of the housing schemes from the 50s are facing modernization, but coordinated knowledge is lacking of how to bring the buildings into the future without compromising the principal preservation values (Dansk Bygningsarv 2015). This brings the headline ´architecture and preservation´ as a highly rated parameter into this paper´s evaluation of both aesthetic and historic values.

The buildings from the period are obviously challenged as both materials, details, cold bridges, joints and the overall aesthetics and a huge amount of buildings must be kept untouched besides from the installations. At the recently published Danish literature of the period the ventilation question is hardly mentioned, but from several case studies from the 50s it is obvious that the question of air exchange can bring these building´s indoor and outdoor expression in danger if not taking properly consideration to the huge damage centralized systems can force. That is basically why we in this paper have focused only on ventilation renewal. Under these circumstances the ventilation devices must be implemented and expressed through a very gentle design. If talking about the façade, the existing façade construction is born with functional perforations such as fresh air canals and filtered masonry to the food store/room. These can be brought in activity in the renovation design.

Through studying this parameter several innovative products have appeared, such as the ventilation window and the integrated parapet solution from Ecovent, see figure 4. Also some products like ventilation windows are very promising constructions for solving the design of the façade (Klint 2009b).

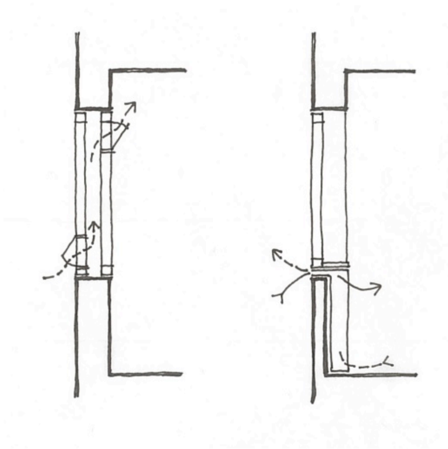

Figure 4: Innovation: Ventilation window and facade solution from Ecovent. To reduce the necessary space required for facade integrated solutions the companies continuingly works with new decentral solutions.

3.2 Space and daylight

Common value based set of norms are existing amongst professional architects regarding a successful experience of architecture: the space should be well defined and proportioned, space should be well lit and the choice of materials should be in harmony and allow the tenants to influence the space with their own selection of arrangement. In addition to this the space should also be designed as extremely functional with good possibilities for furnishing and easy to clean. This means that every disturbing visual installation should be avoided. Both the building regulation in the 50s and a good design ability of the architect shaped the daylight quality. For the future it is important to pay attention to efficient space and to respect the daylight distribution.

The design of the ventilation points in many aspects to the façade ventilation solution. The decentral solution distributing canals to all rooms in the flat, hidden above a hanging ceiling; occupy space primarily in the corridors. Also canals in the rooms can occur. The decentral solutions concentrated under the window inside the heating niche looks very discrete and can be developed to a high aesthetic standard. The decentral solution, described as devices hanging on the wall perpendicular to the façade, will disturb the room feeling. But if integrated under the roof above the window, there will be more discrete possibilities for an acceptable solution. Example of innovation: Change of filters is a huge issue for organizations maintaining the buildings, because this has to be done inside the flat. Also related to this issue it is observed that new innovative filter components are developed. A better insulation value of the window, either 3 layer energy glass or similar will reduce the amount of incoming daylight.

3.3 Energy Efficiency

Energy efficiency in buildings can initiate a mayor renovation, because of the potential annual savings in energy from optimization of the constructions and installations. More than 40% of all surveyed multi-storey housings in Denmark from before 1960 has an energy label D, which is comparable to a maximum annual heat consumption of 150 kWh/m^2/year (Kragh 2015). The heat consumption based on the ventilation of multi-storey housings in the period from 1931 to 1950 is estimated to approx. 25% of the total heat consumption (Wittchen 2004). By using new high efficient counter flow heat exchangers with an efficiency of 80 – 90% such as in the decentralized ventilation systems in case 2 and 3, energy savings as high as 30 - 40 kWh/m^2 per year of the annual heat consumption can be reduced in multi-storey housings from before 1960 (Tommerup 2004).

3.3.1 Energy consumption - Heat

The case studies and the reference building investigated are supplied with district heating. Figure 5 shows the annual heat consumption related to the net floor area for the 3 cases before and after installing the balanced mechanical ventilation system, and for the reference building the consumption before the proposed energy renovation.

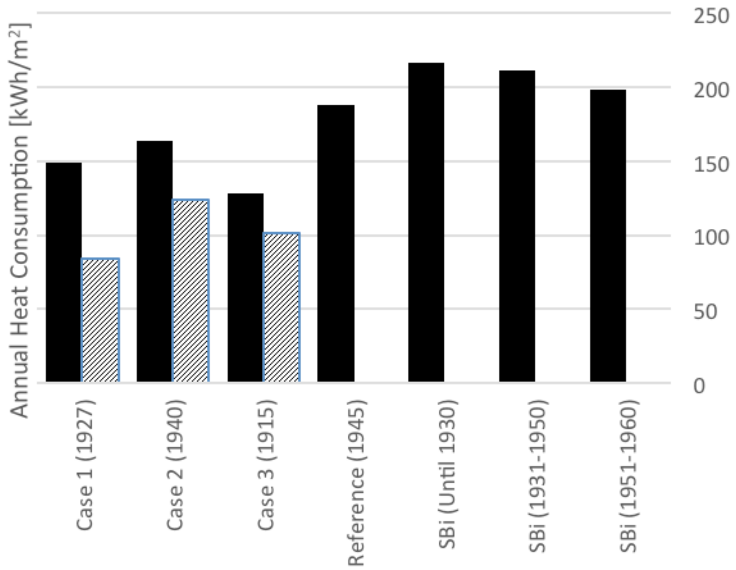

Figure 5: Annual heat consumption before and after renovation

<u>Case 1:</u> This energy renovation is based on balanced mechanical ventilation used with joint intake and exhaust, however there were both central and decentral heat recovery units for the winter combined with natural ventilation in the summer. The energy savings are obtained by preheating the ventilation air in solar low energy ventilation tower to hide ventilation ducts and produce solar energy at the same time.

<u>Case 2:</u> In this case the energy renovation was based on decentralized balanced mechanical ventilation with heat recovery in each dwelling and joint extraction ventilator in the roof space. Solar cells were used to match the electrical consumption of the ventilation units.

<u>Case 3:</u> The energy savings in this case are based on high efficient and low consuming decentralized balanced mechanical ventilation solution in the facade, replacement of the old

windows with new triple layer energy glass and re-insulation of the cavity in the external wall and the story partition.
The average annual heat consumption for multi-story housings in Denmark is based on the SBi-report (Wittchen 2009) on the basis of registration made by the authorized energy labelling consultants in the period from 2005 and 2008. The annual heat consumption in the reference building is based on the registrations from 2013 to 2014 and corrected by the Danish Design Reference Year 2010.

3.3.2 Energy consumption - Electricity

Measurements of the electricity consumption shows that the energy consumption from a decentralized balanced mechanical ventilation unit type V300 from the company Ecovent, which generates a ventilation flow of 45 m^3/h, uses less than 8 Wh electricity comparable with 0,2 EUR per day and an annual electricity consumption of 70 kWh. With an electricity cost of 0,2 EUR per kWh (incl. vat) in Denmark the annual cost for a dwelling with two units is approx. 30 EUR (Klint 2009b).

3.4 Comfort measurements

Measurement of the comfort in existing buildings with newly installed balanced mechanical ventilation shows that the indoor climate generally is improved. However, the comfort parameter of draft caused by leakiness in the climate screen or directly from the ventilation system (both the central and decentralized ventilation solutions) haven't been investigated thoroughly in any of the cases even if the user surveys reveals problems within this area.
Some results show an improvement of the draft problems after re-insulation or replacement of the climate screen; however the draft caused by the ventilation system itself hasn't been covered sufficiently. A research paper aiming at investigating air renewal effectiveness of decentralized ventilation devices with heat recovery (Coydon and Pfafferott 2014) concludes, that even if the ventilation system removes pollutions like CO^2 from the room, the distribution of air and the experience of the air supply is depending on the temperature, speed and direction of the airflow.

3.5 Ventilation rate (carbon dioxid measuring)

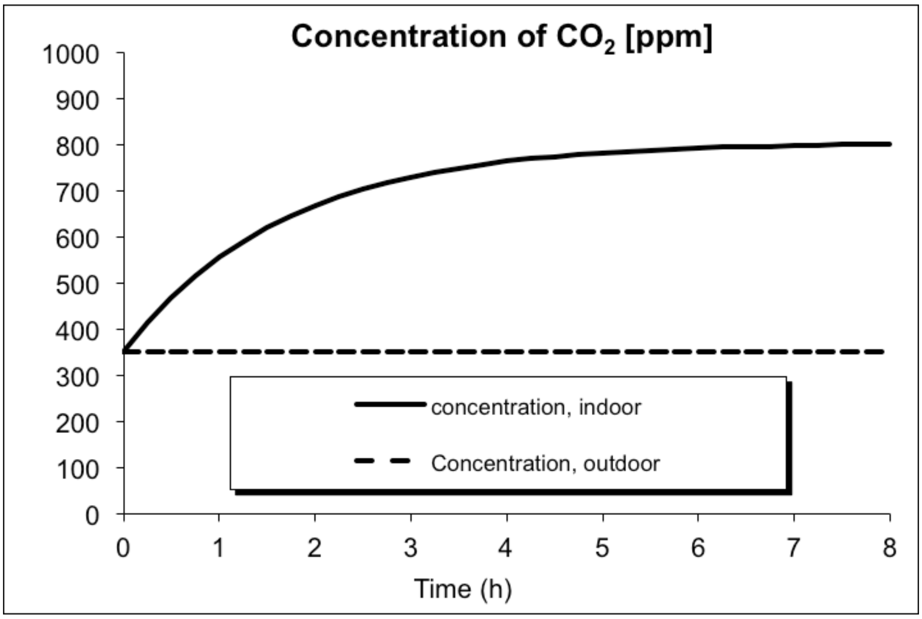

Figure 6: CO_2 concentration progress in case 3.

Figure 6 shows a calculation of the CO2 concentration in case 3 after the dilution principle with an air change of 0,6 h^{-1} corresponding to the measured ventilation amount in the dwelling from the decentralized units. The ventilation efficiency of the decentralized units shows very promising results to comply with the demands, which applies for new buildings in Denmark. However; this has to be documented in a larger scale to have been significance.

3.6 Noise emission from ventilation system

There are no qualified measurements of the noise from the decentralized ventilation solutions, however the units are undergoing a progressive development to reduce the risk of noise, such as optimizing and moving the fans to the primary side of the heat exchanger. The user survey showed no discomfort caused by noise, however a German study in 10 office buildings with decentral ventilation solutions the measured sound emissions in some buildings were above the limits of workspace environments (Mahler and Himmler 2008).

3.7 Users´ survey

In this investigation a user survey was carried out in the reference building with the purpose of comparing a building with mechanical extraction and high potential to saving energy by installing balanced mechanical ventilation with heat recovery.

User experienced dissatisfaction in %	Very often	Often	sometimes	Seldom	Not at all	No opinion
Room temperature	3	14	41	27	12	3
Vertical temperature	13	26	22	27	12	
Draft by the window	13	19	20	32	16	
Draft generally	8	23	17	25	27	
Air quality, smell	7	25	35	19	14	
Air quality, fresh air	1	4	21	31	43	
Air quality, generally	4	39	43	6	1	7
Sound level from int.	12	40	21	13	4	10
Sound level from ext.	3	30	25	23	5	14
Daylight	3	6	17	43	28	3

Figure 7: User survey in reference building

A similar user survey was conducted in a building after the installation of balanced mechanical ventilation with a decentralized solution integrated over the ceiling in the dwelling (Klint 2009b) see figure 7. In the reference building the tenants were generally satisfied with the indoor climate such as the room temperature, draft and daylight quality. However; they experience dissatisfaction concerning the air quality in general and specific when it comes to unwanted smell and noise from the external environment such as neighboring dwellings.

In the survey conducted in the multi-story housing with newly installed balanced mechanical ventilation the tenants generally experienced an improvement with the indoor climate; especially feeling of draft has decreased after the renovation.

In the decentralized ventilation solution integrated in the facade the tenant experienced a much higher comfort concerning the mix of fresh air and had no discomfort with draft, such as before the renovation.

4. Discussion

A movement in the innovation and development of ventilation systems for renovation of multi-storey housing towards more decentralized solutions such as integrated in the facade has been investigated. The parameters from the findings have been discussed in the triangular study and listed according to the starting point of this paper: aesthetic and preservation as well as indoor comfort forms the two paths of our investigation.

4.1 Aesthetic and preservation

- Ventilation doesn't necessary spoil the facade. Possibilities to reuse the existing perforations of the masonry must be taken into account when optimizing the solution. Innovative measures such as the facade integrated ventilation unit under the window (figure 4) can as an example provide acceptable solutions.
- Users must be involved in the renovation to get a higher acceptance of the installations.

- Decentralized ventilation solutions absorb less space for pathways inside the dwelling, which is an advantage to the users.
- When changing the existing windows to triple layer glass the daylight factor most likely will be reduced, however improvement of indoor comfort generally can compensate for this.
- Potential for saving heat, in this case approx. 25 % can accelerate the renovation rate.
- There is a potential for saving electricity compared to central solutions, which can be compensated for with a limited number of solar cells on the roof.

4.2 Indoor comfort

- The indoor climate generally improves with introduction of balanced mechanical ventilation; however, absence of draft must be identified and solved first.
- Possibility to reach a ventilation rate as for new buildings.
- Noise from the devices must be kept under the requirements.
- Users want individual control of the ventilation, which can be made by decentralized solutions.
- Noise from local noise sources, such as traffic, train etc. can be reduced through insulation of the climate screen.

5. Conclusions and perspectives

In the conclusion of the parameter study and the discussions the authors have identified three essential statements:

1. New interdisciplinary working methodologies will improve both quality, quantity and users satisfaction, and the new results will create value.

2. It is obvious that the movement towards development of decentral ventilation stimulates the industry to develop new and innovative products.

3. From the studies a high level of innovative initiatives has been identified, which indicates a movement towards development of more decentralized ventilation solutions in the introduction of balanced mechanical ventilation in the multi-storey housing in Denmark.

Perspectives

- New facade solutions must be developed in a gentle design to solve the perforation of the façade for decentralized ventilation solutions such as new window designs.
- Incoming daylight should not be compromised when changing the façade

- Draft caused by leakiness in the climate screen or directly from the ventilation system should be investigated more thoroughly with focus on temperature, velocity, turbulence and direction of the airflow.
- The ventilation efficiency of the decentralized units should be documented in a larger scale.
- Measurements of the noise from the decentralized ventilation solutions should be carried out.

University of Reading
(email: l.schweber@reading.ac.uk)

Abstract

Construction professionals are continually faced with the challenge of incorporating new technology into their buildings. Much of the current research treats innovations as a discrete entity, thereby overlooking the system properties of many innovations. Implementation often involves extensive accommodation of both the technology and the building. Failure to appreciate this poses significant challenges to the project team, with unintended consequences for the project as a whole. A social construction of technology (SCOT) approach is used to explore the integration of Building Integrated Photovoltaic technology (BIPV) on a commercial project. By exploring the succession of problems and solutions shaping the uptake of BIPV, the analysis also identifies a number of distinct decision modes, including: discrete, conventional and integrated decision making. The first two often contribute to unintended consequences, knock on effects and lock-in, whilst the third is essential for sustainable design. Whereas much of the literature linking sustainability and integration focus on integration across disciplines, this paper links emphasises the need for a holistic understanding of the overlay of different systems constituting a building, including renewable technologies.

Keywords: BIPV, Projects, Innovation, Social Construction of Technology, Co-development

1. Introduction

Construction professionals are continually faced with the challenge of incorporating new technology into their buildings. While much of the research into innovation treats technologies as self-contained entities which can be inserted directly into a building, experience suggests that the process is often much messier. This is especially the case with many of the recent renewable technologies which are systems with multiple components rather than single units. It can also be ascribed to the lack of fit between the requirements of the technology and standard building designs and practice. Far from a simple process, implementation often involves extensive accommodation of both the technology and the building. Failure to appreciate this often poses significant challenges to the project team; decisions concerning a particular design feature in either the technology or the building often throw up new problems, with unintended consequences for the project goals and for the building as a whole. This paper explores these issues by focusing on the micro-level dynamics accompanying the incorporation of Building Integrated Photovoltaics (BIPV). In doing so, it documents the mutual constitution of the technology and the building.

The challenge of green building is often treated as a problem of project team integration, with the focus being on professionals and their procedures and competencies. While this view captures important issues, the focus on professional roles and formal procedures obscures the complex decision making processes which explain how and why challenges are met. In addition, it masks adjustments to both the innovation and the building which accommodation produces. Little attention is paid to how innovative technologies involving cross-disciplinary issues affect the building in which they sit and the processes by which they are installed. What is missing is an understanding of how these interdependencies and the ways they are accommodated come together to shape both the technology and the building.

BIPV offers an example of a technology which is integrated into a building during construction rather than being bolted on during construction. As such, the incorporation of the technology necessarily involves extensive accommodation at many levels and in many different ways as it interfaces with different aspects of the project and its components. These accommodations can be in the form of technical adjustments or through changes to standard designs or ways of working. These technical, design and process-management issues are often treated as distinct and separate but in practice are interrelated.

This paper uses the Social Construction of Technology to explore the ongoing accommodation of both the BIPV technical system and the building. The advantage of this approach is that it draws attention to the succession of problems and solutions which constitute the construction process. By focusing on the actors and objects involved in successive accommodations, it highlights three distinct modes of decision making which inform the uptake of a system innovation at the level of construction projects.

2. Literature Review

Much construction research looks at sector level and macro level innovation; in contrast, this paper focusses on the challenges at the project team level by exploring accommodations to both the innovation and its context as the innovation is implemented. In doing so the paper rejects the notion of linear models of innovation and uptake (Rothwell 1994) and the distinctions between invention, innovation and uptake (Rogers et al. 2001).

A number of papers developed the idea that the effect of innovations varies with the local context. In a well-known typology, Henderson and Clark (1990) distinguished between four types of innovation, based on the relation of the innovation to the firm and its processes; These include: architectural, modular, incremental and radical innovation. Whereas Henderson and Clark focused on the effect of discrete innovations, Slaughter (1998)explored the impact of innovations which are more systemic in nature. Her research classified innovations by their distance from current practice, and their links to other components and systems. She distinguished between the discrete types of innovation outlined by Henderson and those which have system characteristics and which therefore require coordination among the project team, special resources and greater levels of supervisory activity. In a parallel study, DuBois and Gadde (2002) contrasted different types of construction contexts. Their largely conceptual paper distinguished between tight and loosely coupled systems to explain differences in the accommodation of innovations at both project and the firm level. The discussion which follows builds on these arguments concerning variations in the effect of innovations on the local context, be it the building design or the processes through which it is developed and argues for the need to explore empirically the process of accommodation within the project.

The relatively more recent advent of micro level socio-technical studies has contributed significantly to our understanding of innovation implementation in construction. Both Kjellberg (2010) and Harty (2008) used ANT to explore the introduction of innovations at the project level. In a study of the introduction of 3D-CAD software, Harty introduced the concept of relative boundedness to highlight the way in which innovations often have spill-over effects which go far beyond those intended or even anticipated. Harty's study also pointed to variations in actors understanding and thus use of a similar technology. This paper draws on both points, as it explores differences in key actors' motivation for adopting BIPV, their effect on design decisions and their unintended consequences.

An aspect of this problematic can be found in Kjellberg's (2010) study of the impact of a process innovation on the transformation of a warehouse. In his paper, Kjellberg documented the effect of a new warehousing system on both innovation and building design decisions. While, Kjellberg's study focuses on the transformation through implementation of a management system, his argument can be applied to the study of technical, systemic innovations. The research presented below explores the effect of BIPV on the ongoing design of the commercial building into which it was incorporated.

The analysis which follows contributes to these micro-level explorations of the accommodation of building project teams and building designs to the demands of new innovations. In contrast to these studies, the study of BIPV pushes the general argument one step further by problematizing both the design of the technology and the building. It also provides a basis to reflect on different modes of decision making, thus contributing to current understandings of both barriers to uptake and the processes supporting green construction. More specifically, it draws attention to the challenge of integration at the level of decisions.

3. Background

BIPV is a form of photovoltaic technology which is integrated into the fabric of a building. The technology is not fixed in format and in the UK is typically bespoke in design. It consists of several components: the photovoltaic cells which are laminated into the façade/louvre glass, connectors and wiring which take the DC generated electricity from the cell to the invertors, invertors which convert the electricity to AC and an export system which exports surplus generated electricity to the grid. Each of these components have implications for the design of the BIPV and similarly the design of the building will dictate the number of cells used, their configuration, length and location of wiring, position of invertors etc. By considering BIPV as a set of components, it can be considered as a technological assemblage which interfaces with the rest of the building design. Conflicts and resolutions occur as the technology is accommodated within the design and construction of a building. For example, the PV panels are accommodated within the frames of the façade, the wiring has to be concealed within the building and the inverters and metering systems have to fit within both the building and the electrical arrangements of the building.

4. Research approach and method

4.1 Analysis

Social Construction of Technology (SCOT) adopts a socio-technical approach to technological development. Analysis focuses on the networks of actors and objects which form around the specification of problems and solutions in the development of a new technology or, in this case, in the implementation of BIPV into a building (Bijker 2009; Schweber & Harty 2010).

For the purposes of this paper, the approach allows for consideration of the way in which construction professionals deal with problems and their resolution without privileging or distinguishing between types of issues (technical, design or management). It also draws attention to different motivations or criteria for discrete decisions. Although SCOT usually focuses on the development of a single technology, this paper extends the approach to explore the co-development of BIPV and the building in which it is introduced.

The case study, Future Green, is a commercial science centre which incorporates BIPV into the windows to meet its carbon reduction goals. It is one of three case studies in a larger research project; it was selected for this paper because of the very visible and unintended consequences which the introduction of BIPV had for the appearance of the building. Data collection combined semi structured interviews and document analysis. The project was identified by the supplier of the PV panels and contact was first made with the project architect. Snowballing was used to identify participants, until no new project members were identified. In total 13 construction professionals were interviewed. The research received ethics approval from the University of Reading and was carried out in line with these requirements.

Thematic analysis using NVivo 10 focussed on identifying problems and solutions arising during the project. In addition, attention was paid to the range of different considerations which led to particular decisions and their impact on the co-development of the building and the BIPV technology. Diagrams to explore the sequence of problem and solutions throughout the build were drawn up and problem solving strategies were identified.

As a method, SCOT provides a basis to explore discrete decisions and their effect on the development of a technology; however, it is less good at identifying the effect of broader structural characteristics which shape the process (Klein & Kleinman 2002). In the case study discussed below, the use of SCOT may have obscured issues of project organisation, path dependencies or management styles, which indirectly influenced particular decisions.

5. Future Green

The case study, Future Green, is a commercial science hub which is the first stage of a mixed development which includes the science hub, commercial offices, retail outlets and residential housing. The client group included a university and a city council, along with several other strategic partners. Future Green is a seven floor mixed space building, including exhibition and office space. Occupants, renting the offices are expected to be start-up businesses within the field of sustainability. Although predominantly council owned and run the building is operated by a private company which is in charge of letting space and running the building.

The project started out as a flagship sustainability project and BIPV was used to support this statement. BIPV panels were incorporated into ten of the 12 windows on the south-west elevation of the building. Other sustainable features included a small solar thermal installation on the roof of the building, a green roof and green wall on the west elevation and natural ventilation on the upper floors. The building includes many irregularly spaced, tall, narrow windows which make a bold architectural statement against gold cladding and green vertical brise-soleil panels. The project was carried out under a design and build contract.

The analysis which follows describes the co-development of the BIPV panels and the building, from the perspective of key design decisions and the socio-technical network which supported them. Figure 1 provides an overview of the process of co-development; while Figures 2-5 present enlarged (more legible) sections of the diagram to support the discussion. Each shaded box represents a decision or action which shaped either the building (the top line of boxes) or the BIPV (the bottom line). The unshaded boxes mark key points in the co-development story.

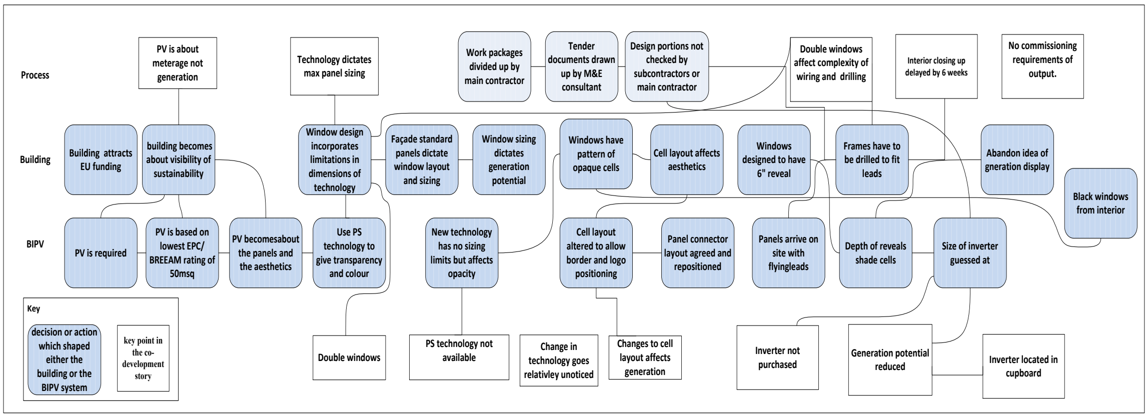

Figure 1 Co-development of BIPV and Building:

As Figure 1 indicates, the integration of BIPV is analysed as a succession of problems and solutions which led to the integration of BIPV within the window panes as a distinctive element of the glazing. Far from a simple decision, discussions around this feature passed through phases, each of which involved a slightly different problem and associated set of actors, objects and considerations. In the early stages, the architect proposed the use of thin film PV technology. During the tender phase, procurement problems led to their replacement with conventional monocrystalline cells, but knock-on effects on frame design and glazing beads were not picked up until well into construction, resulting in delays and re-work. The discussion which follows traces this decision making process.

5.1 Choice of technology

The introduction of BIPV was initially informed by the clients' early decision to attract European Regional Development Funding (ERDF)[1]. Conditions for the funding included the achievement of a BREEAM Excellent and preferably BREEAM Outstanding rating as well as an Energy Performance Certificate (EPC) rating of at least B and preferably A. Both A and B EPC ratings required the use of renewable technology.

Early on in the project, the client, architect and lead mechanical building services designer held a review of the sustainability options with a view to selecting which technologies to use. The architect and client were intent on using highly visible forms of sustainable technology so that future tenants and the general public would see that the building was green; they favoured the use of green walls and roof and solar technology (both solar thermal for hot water and photovoltaics (PV) for electricity generation). The design team considered using a conventional roof mounted PV system, but realised that the green roof would shade the panels. Instead, they suggested mounting them above the roof parapet, but this was rejected as it would not have been acceptable to the planners. In addition the PV panel frames would have had to be fixed to the roof, which would have necessitated piercing the green roof membrane and would have

[1] https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/9455/National_ERDF_handbook.pdf (INCORRECT REFERENCE)

threatened water tightness. There was room for a small solar thermal installation on a separate part of the roof, but the space available was small and incompatible with a roof mounted PV system. Following these reflections the team decided to use BIPV.

Under the initial proposal the building with BIPV was set to achieve BREEAM Excellent and B for its EPC rating. For the reasons stated above, the client wanted an A rating and thus asked the mechanical engineer to come up with a design solution. He found that while only 50 square meters of PV panels were required for a B rating, 260 square meters would be needed for the desired A result. The client decided that a B rating would be acceptable, but still wanted BIPV as part of the project.

The choice of BIPV product and its positioning resulted from a succession of considerations. The architect wanted to incorporate BIPV on the large south-east elevation which was visible from the street. After looking at the building layout and the layout and positioning of brise-soleil louvres on the south east, the mechanical design engineer advised against this option as the façade had already been designed with large vertical brise-soleil louvres which would have shaded the panels and reduced efficiency. The two professionals considered incorporating the PV into the brise soleil louvres, but rejected this on cost grounds and eventually settled on using BIPV in the windows of the south-west elevation which had no brise-soleil louvres. The architect decided to specify thin film PV technology which, despite being of a lower efficiency than conventional monocrystalline technology, would give some transparency to the windows and also allow the windows to be coloured bark brown and so add to the sense of drama.

As indicated above, the decision to include a BIPV system was driven by the client's desire for a building with a strong sustainability statement, the planners' concern for energy generation and an appreciation of the interdependence of different components of BIPV and the building Figure 2 shows how the bid for EU funding and the client's wish to make a strong visible sustainability statement drove the inclusion of BIPV on the project, which then moved the frame through which the actors viewed the technology from one of electricity generation to one of visibility. This drew the architect and designers to using BIPV in the windows and so made the choice of thin film technology desirable. Decision making was thus driven by a dialogue between different actors, with different motivations. All of the actors involved were aware of the range of different considerations and the negotiations supported a well considered decision, taking into account the systemic properties of the technology and the building design.

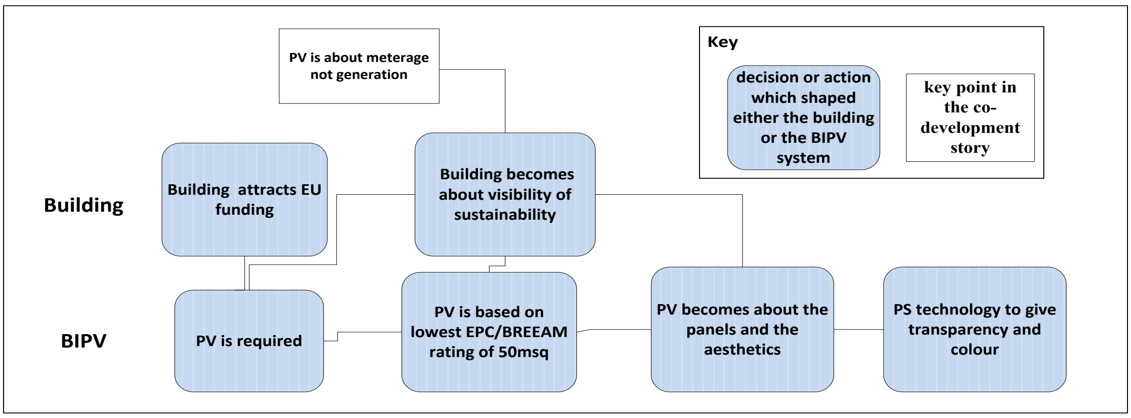

Figure 2: Choice of technology

5.2 Allocation of work packages

The process of developing tender packages for the project was also problematic. The project team continued to design the building, with the mechanical design engineers and architect developing the technical specifications and the main contractor deciding how the contracts for tender were to be allocated. When dividing up the work packages for tender the main contractor decided to include the BIPV panels in the envelope tender package and all the other parts of the BIPV system in the mechanical and electrical package for the internal work of the building. In doing so, he privileged conventional building practice over the technical requirements of the technology.

> It made perfect to put it into the envelope package, because it's no different to installing any other window, it's just got the PV components within it.
>
> Main Contractor

The M&E design consultants drew up the tender packages accordingly and included substantial design portions in each tender package for development of the design for the configuration of connections on the panels, location and sizing of the inverters and wiring from the panels to the inverters. The consultant was very clear that further integrated design between the M&E contractor and the façade supplier would be necessary to make the technology work.

> They have to liaise quite closely with the architect over the installation details, because it would ultimately be part of the façade installation, the two would have to come together and form an integrated solution.
>
> Mechanical Design Engineer

The packages went out to tender and were duly awarded. The main contractor was not aware of the requirement for detail design of the system and the contractors had not read the detail of the specification. The façade supplier viewed the PV panels as just another sort of glazing panel and this resulted in the PV panels arriving on site with two flying leads on each panel and no plan about how they were to be incorporated into the façade and penetrate the building. Some windows were mounted one above the other and this double height design made the installation even more difficult. At the same time the M&E contractor had neglected to plan how the wiring was to run from the frames and had forgotten to order the inverters. Figure 3 shows how this progressive lack of integration and design led to a delay of the internal finishing of that elevation of the building of six weeks.

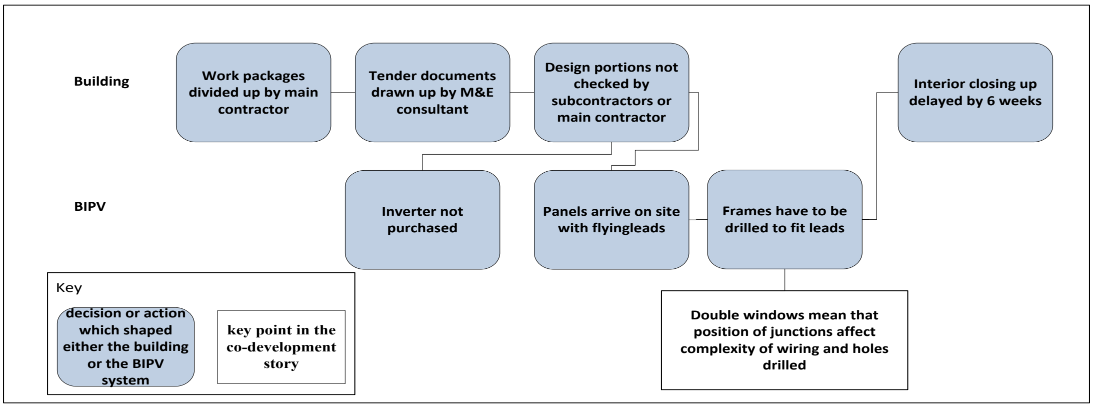

Figure 3: Allocation of work packages

5.3 Change of technology

During the tender phase, the thin film technology was replaced by conventional crystalline cells as the original system proved to be unobtainable. As the discussion which follows and figure 4 indicates, the architect made this decision based wholly on aesthetic considerations, with no consideration for the knock-on effects of his decision. It was only well into construction that the effect of using the more conventional monocrystalline cells on frame design and glazing beads were picked up, resulting in delays and re-work. In the end, BIPV contributed to a strong visual statement from the outside, coupled with a significant loss of functionality from the inside. The BIPV windows were opaque, reducing visibility, and their energy generation was extremely low. The exterior of the finished building clearly showed the inclusion of BIPV in the windows, but internally this was translated into a loss of functionality – both in terms of the transparency of the windows and in the very low PV generation. An account of the substitution of the BIPV product explains how this less than optimal outcome happened.

When BIPV was first suggested, the architect and engineers opted for a thin film technology on both functional and aesthetic grounds. As the architect explained, the brown colour of the panels would resemble wood bark and contrast with the gold façade while the translucent finish would provide light through the windows. The thin film technology had limitations in terms of the dimensions that could be manufactured; this meant that most of the PV windows would be made from two panels, one above the other. In addition, the standard glazing panel sizing for non PV windows dictated the window layout and sizing.

During the tender process the thin film technology became unobtainable and the supplier proposed to substitute it with conventional monocrystalline PV panels which would provide slightly superior PV generation, but which were not transparent. Transparency would be provided by the spacing between the PV cells, rather than as a general translucency across the whole panel. The architect and main contractor were keen to keep to the schedule and agreed that the new technology be used. The architect worked with the glazing supplier to optimise the layout of the cells and logo to have an even border and symmetrical cell spacings. The architect was unfamiliar with the differences in the two technologies and summed up the situation:

> The only difference as far as I know with that is it's the graphical display of the cells… the original specification that we had was more of a bark wood type. … it wasn't a massive issue, we just went back to an alternative specification.
>
> Architect

The knock on effects of this decision was that the changes to cell spacing affected the generation potential of the technology and the aesthetics of the windows from the inside. Instead of a semi-transparent brown wash, up to 80 % of each PV window now had blocks of black opaque cells. The other thing to pass without notice was that the restriction on the dimensions of the technology no longer applied, such that the windows could have been specified as one panel, thus reducing the number of joins and flying leads.

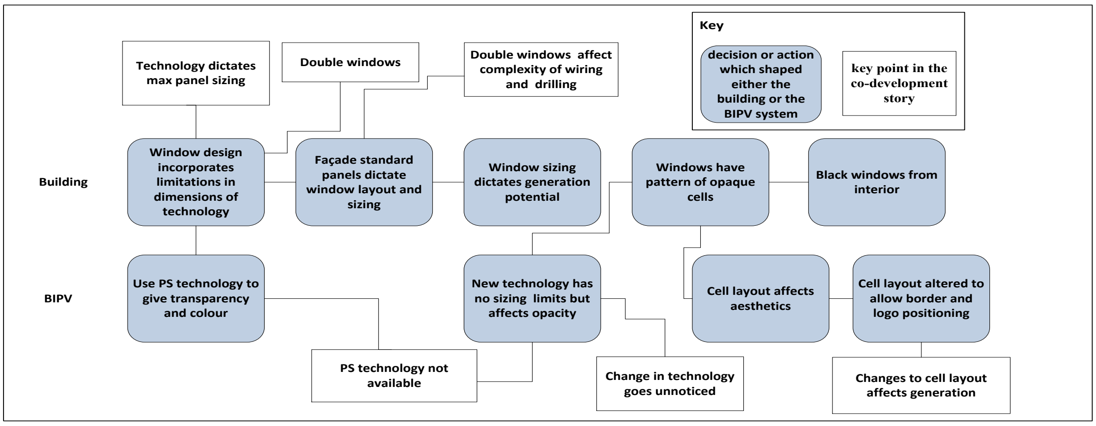

Figure 4:Co-development of building and BIPV

During the construction phase the lack of design and coordination of the BIPV system led to rapid discrete decisions being taken over frame modifications, glazing beads and wiring configurations. These decisions sub-optimised the output potential of the system and resulted in delays and re-work. In addition, an aesthetic detail for deep window-reveals resulted in shadowing of the PV cells during significant periods of the day which dramatically reduced generation further.

6. Discussion: Modes of decision making

Over the course of the project a series (and sometimes parallel set) of problems and solutions led to the co-development of the building and the BIPV. Finally, the incorporation of BIPV into the building reduced internal visibility and resulted lowered PV generation, effectively transforming BIPV from a renewable technology to an external sustainability statement.

Reflecting on how this happened, the succession of problems and solutions discussed above point to three distinct modes of decision making, including: discrete decision making, conventional decision making and integrated decision making.

Discrete decision making occurs when decisions are taken in isolation without reference to the rest of the project. In this mode, decisions are made based on the immediate situation, where immediacy refers to both the spatial and temporal dimensions. In the decision over the choice of technology, the architect addressed the issue based on his aesthetic concerns. He selected the thin film technology because it gave a semi-transparent window and because its brown colour added to the sustainable look of the building. When the technology was no longer available from the original supplier, he agreed to substitute it with monocrystalline cells, without considering that the PV technology was only one part of the larger BIPV system. As the discussion above indicates, this discrete decision had a number of knock on effects. Not only was the generation capacity reduced, but the windows became opaque. Collateral damage also occurred when original size limitations on the windows no longer applied, but were kept in the design, thus complicating wiring configurations and when the size of glazing beads needed were not altered to fit the new, thicker panels.

The term ‘conventional decision making’ refers to decisions based on standard procedures. Unlike discrete decision making, this mode takes into account broader temporal and spatial considerations, but not the specificity of the technology and the building. Like discrete decision making, this mode fails to take into account the knock on effects of the changes to components of the technical innovation. In the case of Future Green, this mode is evidenced in decisions around the procurement of technical components and the division of labour into work packages.

As the discussion above indicates, the main contractor divided up the tender work packages based on the conventional division between the envelope package and the internal mechanical and electrical fixing work. The M&E consultant was asked to draw up the work packages and allocated design portions within the packages. The result was that the visible aspects of BIPV were included in the envelope package, whilst the hidden part of the BIPV (the electrical part) was buried within the M&E package, where the design portion including sizing and procurement of the inverter was forgotten. Not only were the electrical components forgotten, but, also, the interfaces between the glazing units, the frames and the internal wiring were not considered until installation; consequent problems took six weeks to resolve.

The third mode identified in this study is integrated decision making. This involves collective consideration of the system properties of both BIPV and the building and is illustrated in the development of the initial bid for EDRF funding. In preparing the bid, the client, architect and M&E designer looked into the implications of using different forms of sustainable technology. They clarified the implications of installing a green roof and of using solar thermal installations and, based on these considerations, agreed to use BIPV on the façade instead of roof mounted PV panels. The decision to use BIPV in the windows was made once the requirements for an EPC rating of B were understood and the square meterage of PV matched the window sizing. The south west elevation was chosen for the BIPV as the implications of using the south east façade with its brise soleil panels and consequent shading was unsuitable. All the team members were in agreement that BIPV windows were the preferred solution and understood that from that point the BIPV was primarily about making an external sustainability statement, rather than making a contribution to energy generation.

A second example of the integrated mode can be found in a coordinated response by multiple project team members to on-site problems. This type of flexible, local problem solving is widely recognised as a strength of the sector. In the case of Future Green, the conventional decision to separate the procurement of BIPV into mechanical and electrical packages and the subsequent isolation of the PV glazing from the frame led to a series of on-site issues ranging from how to incorporate the flying leads into the frame and take them inside the building to how to complete the weatherproofing of the envelope when the PV glazing beads were the wrong size. As the different subcontractors were brought together by the main contractor, an integrated decision mode was developed which allowed for innovative solutions to be found.

By analysing the use of these three decision making modes across the implementation process, it becomes easier to understand how and why problems arose in the incorporation of BIPV and why the project failed to deliver on its initial aims. Far from being unique to this project, the argument is that these dynamics are characteristic of innovation in the construction sector. In the case of Future Green, the integrated mode used at the beginning of the project allowed the team to focus on the issue of sustainability as a whole. This led to a holistic solution with clear specifications for the proposed BIPV system. When the thin film PV technology proved to be unavailable, the architect adopted a discrete decision making mode and agreed to the substitution of monocrystalline cell technology, without linking the decision back to issues of generation or functionality which stemmed from this decision. The main contractor's use of the conventional decision mode in deciding work package allocations set the scene for a fragmented development of the BIPV system and a series of problems at the interfaces of both the BIPV system and the contractors on site. Integrated decision making helped to address the local issues on site and encouraged some innovative problem solving, but it could not impact the effect of earlier discrete and conventional decision taking which locked in an opaque windows and low generation outputs from an early stage for the project. The "crown jewels" were indeed installed in an eye-catching setting, but despite good intentions, proved to be hollow when viewed from a point of functionality and value.

7. Concluding Comments

In closing it seems incumbent to return to the initial research problem and ask what this analysis contributes to an understanding of technical innovation in general and sustainable innovation in particular. On one level, it documents the complexity of the decision making process and the co-development of system technologies and buildings. On another level, the distinction between modes of decision making provides the basis for a more nuanced understanding of how 'integration' might address the challenge of sustainable construction.

Whereas most scholars focus on the integration of project teams, this study suggests that formal managerial changes are far from adequate. Sustainable construction depends on a shift in the mode of decision making from discrete and conventional decisions which, while they have the benefit of efficiency, threaten to undermine client and project goals for the new technology.

The challenge is for project teams to recognise the interfaces of the technology and identify which mode of decision making is most appropriate. In the study of innovation and uptake this raises the question: "under what condition do teams engage with an integrated mode of decision making and what can be done to encourage it?" It also raises the issue of the role of contracts and formal structures and procedures in promoting conventional decision modes rather than integrated ones.

Abstract

Most of the building stock in Europe has been built in the sixties and nowadays it is not always fulfilling current requirements coming from binding laws, voluntary standards and clients' needs. When dealing with assets acquisition or with decisions on their reuse and refurbishment, it always takes a big effort just to understand if a building complies with current regulations, because of the lack of knowledge and laws complexity and jeopardising. This paper shows a tool able to help users dealing with the requirements compliance checking of existing buildings. The purpose of this tool is to enable decision makers in making strategic choices about their assets, by providing them the actual state of the building regarding the requirements compliance. The tool consists in a set of checklists, tailored for building function and declined in all the possible type of spaces of the building; this because each space has specific requirements to fulfil, as well as the building itself (intended as an entity). The tool uses as an input spaces dimensions, performances, characteristics but also documents and permissions; with a calculation procedure, it gives to the user a set of data. This kind of check is fundamental to take decisions about how to conduct the asset: refurbishment, handover, retrofit or simply maintenance are all options that can be evaluated only with the correct knowledge of the asset. A preliminary case study is presented here just to show the potential of this tool; to improve the compliance checking process, some characteristics (that can be automatically checked) have been implemented in Solibri Model Checker. The remaining have been checked manually with other software and all the results have been collected in the checklist developed. This tool is part of a bigger work that wants to look not only at the requirements but also at the physical state of the building (so to organise maintenance), the energetic behaviour (so to optimise consumptions) and at the adaptability potential (so to evaluate functional change alternatives).

Keywords: Asset management, requirements compliance, real estate, BIM, IFC

1. Introduction

Most of the time, especially for new constructions, checking available documents is sufficient to provide a clear situation of the compliance with laws and standards of the building under analysis. But dealing with the real estate means to face modifications occurred over years, missing and not updated documents, compliance with new standards and in general with a lack of information (Montague, 2015). This is the reason why most of the times it is necessary to review the response of the building and its spaces to mandatory and even voluntary requirements, given by either laws, regulations, standards, guidelines, clients and owners.

Therefore, it is necessary to go beyond the analysis of pathologies, service life and documents: it is necessary to provide users with a clear framework of the building compliance to requirements, divided by function (both of the building and of each single space inside it). So the objective is to create a checklist, easy to fill (no need of professionals for most of the controls), able to return to the user a clear understanding of the building, to allow, if need be, planning restoration and adjustment works.

This is also strictly related to building adaptability (Kelly *et al.*, 2011): as adaptability is the ability to accommodate changes, requirements fulfilment is a pre-requisite, necessary to allow these changes. An example is given by building functional change: a building may change its function more than once during its useful service life (Kincaid, 2000), but, even if it is technically possible, maybe the adaptation is not allowed. So this type of check completes the adaptability assessment, giving to users the possibility to plan operations not only to restore defects and pathologies, but also to restore the compliance with binding laws. Compliance checking can be also performed during the handover, both by the seller as a guarantee and by the buyer as a control.

This paper shows, after a brief state of the art related to regulatory compliance and code checking, the tool developed by the authors, with the help of a case study (an existing office building). The paper contains also a short explanation of the assessment and calculation procedure of the tool and the discussion about results generalisation and limitations.

2. State of the art

Here it is a brief description of the state of the art related to regulatory compliance in general and to code checking with automated (or semi-automated) software, in connection with BIM models. Even if using a BIM model to perform this kind of checking is not mandatory, project complexity is become so critical that needs to be handled with dedicated software.

2.1 Regulatory compliance

Regulatory compliance checking is an activity done mainly during design stages, with an increasing complexity from the brief to the final design stages; this checking is made also after construction, to check the compliance between what has been designed and then built. In a perfect world, all these data about requirements can be easily checked in the documents or directly in the building, but with the Italian real estate, built mainly in the sixties with different laws and standards, performing this check is not an easy task.

The due diligence, defined in the ISO 26000:2010 as the "*comprehensive, proactive process to identify the actual and potential negative social, environmental and economic impacts of an organization's decisions and activities over the entire life cycle of a project or organizational activity, with the aim of avoiding and mitigating negative impacts*" can be the solution to the problem. Due diligence can have wider objectives, allowing to assess several aspects of a building through an audit (defined as a data gathering procedure); also Building Condition Assessment (Re Cecconi *et al.*, 2014) can be considered a technical due diligence, as the regulatory compliance checking.

Even if this assessment spaces on a really wide range of topics (fire fighting, safety, accessibility, comfort, etc.), the evaluation process is quite straightforward and simple: a complex assessment system with weights, categories and tools is not mandatory to perform a good check; nevertheless, the complexity of the laws and standards frameworks is pushing the need of software able to automate these checking, which now imply a huge effort for designers (Malsane *et al*., 2015). On the opposite, there is the need to pay great attention to the requirements to be checked: a requirements database must be provided, so to have the possibility to check their fulfilment, space by space and for the entire building. Even if not related to buildings, an interesting example is given by Maxwell and Anton (2009), which provided an assessment system dedicated to a health record system, able to check the requirements against the current U.S. law.

Requirements can be associated to the part of the building they are related to: building (as a whole), spaces and components (including subcomponents). Building (as an entity) has to be considered in relation with surroundings (other buildings, landscape, viability, etc.), but also some characteristics have to be checked on the whole building (number of exits, height, extension, etc.). Spaces are really important for requirements compliance: most of the times the function of the space influences the requirements, so a careful space-checking must be done. Components must have some characteristics depending on the building/space function, but some requirements are also connected to single layers (especially finishing, load-bearing elements, insulations, etc.), even if they can be easily transposed to spaces. Eventually, to perform a proper requirements due diligence, many aspects must be checked, some of them can be generalised, but many others must be checked depending on the specific building.

Requirements fulfilment, together with a price list, maybe appositely implemented, can provide to the client and to decision makers the clear situation of the money to be paid to restore the building compliance, if need be, or to change the function of one or more spaces, which is a frequent activity, especially in offices and commercial assets (Kincaid, 2000).

2.2 Code checking

Going further with this topic, together with the requirements database, a tool to automatically check them should be provided: this because buildings complexity is always increasing and doing this check manually is becoming more and more hard-working. A solution to this problem can be given by Building Information Modeling (BIM) that, together with the IFC protocol (BuildingSmart, 2015), provides an instrument to ease these kinds of controls. Maxwell and Anton (2013) provided a demonstration of the potential of the code checking procedures, by applying them to a water distribution system. Malsane *et. al.* (2015) tried to translate (and optimise) the rules related to fire safety for dwelling houses in England from textual rules into computer-readable rules; as can be seen from their work, the code checking is not only a matter of using a software, but the comprehension of the rules (and the consequent transposition) is very important. This leads to the need of having a proper database of regulatory requirements to be used, not depending on the automated compliance checking tool to be used.

Despite the importance of BIM code checking, Cao *et al.* (2015), by analysing 106 BIM projects in China, state that BIM is used mainly for design (fabric and services), clash detection (during construction stage) and not too much for checking the design against building codes. Anyway the interest on BIM is constantly increasing (Market Research Reports Inc., 2015), so also this task will be soon more important.

Code checking can be performed also as an audit connected to Facility Management (Dimyadi *et al.*, 2015); authors presented methods commonly used to represent and access digital regulatory knowledge for compliance audit purposes and claimed for an open standard regulatory knowledge representation.

Solibri Model Checker (SMC – Solibri, 2015), one of the most famous instruments to performs these checks, can be given a set of rules to be applied to the building under analysis, so to check requirements and create a report (Solihin and Eastman, 2015). Also regarding BIM technologies and code checking, Dimyadi and Amor (2013a and 2013b) and Dimyadi *et al.* (2014) provided interesting data.

Not all the requirements can be easily automatically checked. As instance SMC does not make calculations, which are frequently asked during regulatory compliance checking. This is way the first part of this research focused on the definition of the requirements in a clear and comprehensible way, not related to the tool to be used to perform the check.

3. Information management

The assessment of requirements fulfilment (by law, voluntary, by the client – related to the whole building and to each single space) is a direct consequence of the current state analysis of pathologies and documents, as it completes the building picture. Requirements analysis, guided by a set of sheets and a procedure, is fundamental to understand if the building, not depending to the documents describing it, respects the laws and fulfils the function it is designed for. This analysis includes the control of:

a) requirements of each single space of the building;
b) distance among/from spaces;
c) requirements of the building as a whole;
d) distances among/from the building and other buildings and surroundings.

It is important to notice that requirements have been collected in a database for each single building function, i.e.: office, commerce, cinema, catering, school, etc.; in this way a detailed list of requirements has been obtained, updated to the law in force and attributable to each single (fundamental) space for each function.

This instrument can be used both during the design, as a checklist to control requirements fulfilment, and during use, to check their fulfilment in course of time. In addition to these two main uses, it can be an important instrument to verify the function change, even of only a part of the asset, to assess the compliance to new requirements, as it makes available the reference regulatory framework, with the related operations necessary for the refurbishment; costs can be associated to these operations, allowing to assess in a complete way the opportunity of a functional change. An assessment of this kind has several applications regard safety issues, both regarding the whole building and the activities inside.

Requirements compliance is an important theme, especially if an entire portfolio is considered: through the spaces use and the compliance of their requirements it is possible to plan modifications and so the budget for adaptation works (possibly in connection with other maintenance works).

A future development of this system is given by the possibility to assess the efficiency in space use: it is sufficient to think about how many spaces are not adequately capitalised; having the complete picture of the spaces could help in managing them at their best, avoiding waste and consequently missed incomes. The index under development can help in different situations:

a) to provide the requirements compliance situation of the portfolio, asset by asset: define the operations to be done to restore the portfolio requirements compliance;
b) to provide the requirements compliance situation of the asset, with the list of missing requirements: define the operations to be done to restore the asset requirements compliance, category by category;
c) collect professionals and operators to act properly.

4. Requirements index

Regulatory compliance checking is part of a broader condition assessment tool, involving physical (pathologies, ageing), adaptability and documents checking. Nevertheless, this part can be also used as a stand-alone assessment system. This study is now focused on tertiary office buildings, but other functions (food services, hospitals, residential, hotels, etc.) are under analysis. Buildings dedicated to tertiary activities (offices in this specific case) have been firstly analysed to get the complete list of possible spaces and zones involved (i.e. from Neufert, 2013), then a requirements list, space by space (and for the whole building) has been created starting from current Italian laws and standards. The process of this checking consists of four main steps (Figure 1):

a) Survey of the physical asset, made of the asset itself and a series of documents and drawings;
b) Creation of the digital asset, consisting of a Common Data Environment (CDE), in which information are stored in BIM models and digital documents;
c) Checking of the requirements compliance with current standards, laws and client's needs. This is done automatically (e.g. with Solibri Model Checker) or manually (when an addition data elaboration is needed);
d) Reporting of the situation and, if need be, restoration of noncompliances.

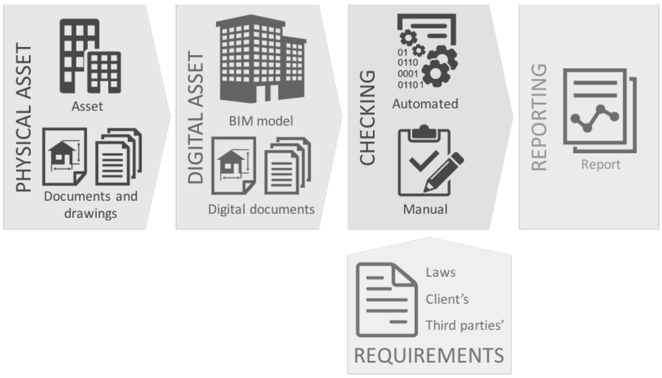

Figure 1: Scheme of the process

4.1 Requirements database

To create a metric for space requirements compliance checking, a database with a precise set of requirements is needed. This should be done incrementally: a complete set of requirements for all spaces and building functions is hardly achievable in a short term. But a robust framework can be designed to gradually collect data in an efficient and effective way. This database is only the aseptic collection of requirements, which should be declined for each specific building under assessment. Each requirement is connected to a specific space and building function (remembering that many spaces can belong to different buildings functions). Each space should be unequivocally defined (e.g. an office with less than 5 people may be different from an open space office with more than 20 people). Here it is the list of data that should be gathered:

a) object of the control: short name of the parameter to be checked (e.g. minimum floor area, maximum number of people, etc.);
b) condition of requirement satisfaction (e.g. minor than, equal to, greater than, etc.);
c) threshold value;
d) internal threshold value, given by the client, to be considered valid only if more restrictive than the threshold value given by law or voluntary standard;
e) unit of measure of the threshold value;
f) source/reference of the requirement, split in three types (each category is associated with a weight): binding law, client's need and voluntary standard;

g) type of control (this leads to different data to be checked and inserted by the operator to verify requirements compliance): visual, documents, calculation, distance and connections;
h) building type: existing building, new construction or both;
i) measuring criteria, the precise definition of how to measure the parameter to check requirement compliance.

In Figure 2 there is an extract of the database created.

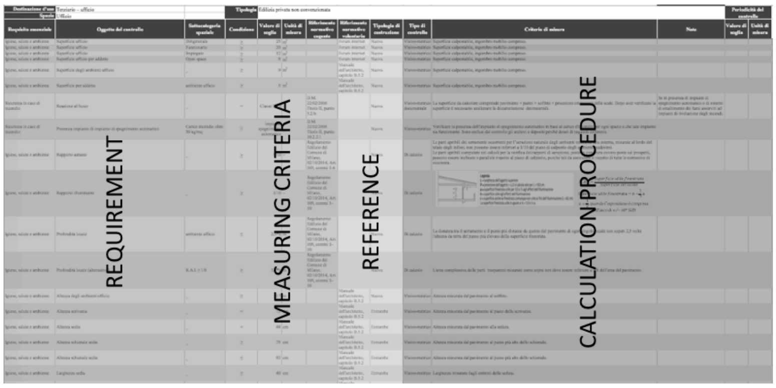

Figure 2: Extract of the requirements database for office buildings

Totally 236 requirements have been collected and associated to 9 major spaces and to the whole building; most of them are the same for many spaces, so the total number of requirements could be reduced to a handier number, if considering that they partially overlap in many spaces. 15 documents (standards and laws) related to office buildings have been checked to provide this list of requirements.

4.2 Space level

The space level is the first level of calculation of the requirements compliance. In this step the requirements database is connected to a specific building and to specific spaces inside it. The data listed above remain the same (they cannot be modified) and additional information must be added. Here it is the list of additional parameters to be filled, once selected the specific space:

a) space data, necessary to unequivocally identify it: number, name, code, space function, space typology, space net floor area, space gross floor area, measured value, document reference, requirement compliance: Y – Yes, this space requirement is fulfilled, N – No, this space requirement is not fulfilled, NC – Not Checked, this space requirement has not been checked and NA – Not Applicable, this space requirement is not applicable to this specific space;
b) adaptation, the need of adapting the space to fulfil actual and future requirements.

After the completion of all the relevant data, for each space, some indexes and key information can be calculated automatically, to define the space requirements compliance. Here the main steps to be done are reported:

a) each requirement, depending on its source/reference, has a weight (to be fine tuned with one or more case studies): 0.6 for binding law requirements, 0.3 for client's need requirements and 0.1 for voluntary requirements;
b) the weighted sum of all requirements (from 1 to n) needed is the maximum weighted Space Requirements Index;
c) the weighted sum of all requirements (from 1 to n) compliances is the current weighted Space Requirements Index;
d) the weighted Space Requirements Index is the ratio between the maximum and the current situation;
e) as the only index may be not enough to understand requirements compliance, other statistics can be extracted.

Eventually, a graphical representation of the results is a good way to understand each space situation at a glance. The red part of the Figure 3 shows the remaining score to achieve the sufficiency, given by the lack of compliance to binding law requirements.

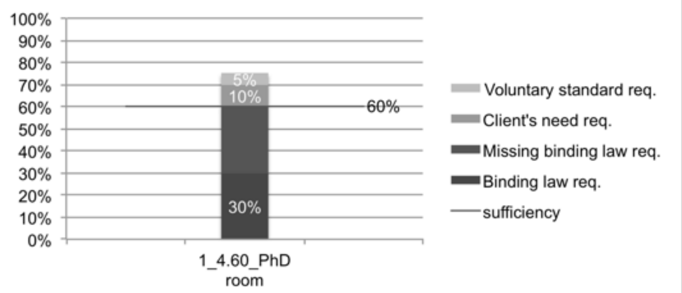

Figure 3: Example of output of the Space Requirements Index

4.3 Spatial unit level

A spatial unit is the collection of all the spaces with the same function. At this level no data are required to be filled by the surveyor. This level is fundamental for understanding building behaviour but there is the need to converge to a single result (or a small set of data); so it is explained the decision of keeping as many data as possible at the space level, using functional units and building levels only for calculations. For each function, the weighted Spatial Unit Requirements Index can be calculated as the weighted summation of the index of each space, using the the net area as a weight, which allows to consider the economic importance of the space, as it is related to the unitary cost; in addition, it is easily quantifiable and objective. Also at this level, interesting statistics about the regulatory compliance can be extracted from the assessment model. Also in this case it is possible to associate the index with a graphical output.

4.4 Building level

This is the last level of calculation of the requirements compliance index. The weighted Building Requirements Index can be calculated as the weighted average of the index of each spatial unit, using the net area as a weight, which allows to consider the economic importance of each spatial unit, as it is related to the unitary cost; in addition, it is easily quantifiable and objective. Another possible weight to be applied (instead of the net area) is an importance weight calculated with the AHP technique. The same statistics done at the functional unit level can be done also at the building level, to fully understand building current requirements compliance situation. Also in this case it is possible to associate the index with a graphical output.

The calculation procedure briefly outlined here is still under analysis and some changes will be applied after testing the it on some case studies. In addition to this, one of the best ways to perform a regulatory compliance checking is to create a BIM model (with a BIM authoring tool) and check it with a code checking software (e.g. Solibri Model Checker); this procedure perfectly works for most of the geometrical requirements, while it has some problems with analytic and textual data. Some of these issues and reasoning are reported in the §5, thanks to the application to a case study.

5. Case study

The case study aims to show the procedure and to make some preliminary tests. The objective is to test the regulatory compliance checking tool in combination with SMC. The combination of the checking tool with SMC (manual and automated checking in Figure 1) is necessary, as not the totality of the requirements can be checked with SMC. This case study has to be considered just a first step of this research, which consists of a wider programme, including building condition assessment and adaptability ratings; the final objective is to provide a complete and exhaustive view of an asset and of a portfolio. The building under analysis is an office building of the Politecnico di Milano. It has been built in the sixties as a steel warehouse and then converted into an office around 25 years ago. It has 3 storeys above ground and one under ground. Spaces are mainly dedicated to offices (for both researchers and administration), meeting rooms, rest rooms and connections (corridors, stairwells and lifts). The building has been refurbished in both fabric and services, so there is no urgent need to act to solve problems. The limited number of spaces, spatial units, the availability of data and drawings and the regular shape make this building a good case study to perform a preliminary test. The building is composed by totally 154 spaces, including shared spaces, rest rooms, technical rooms and storages. The BIM model (Figure 4) has been implemented with the following characteristics and components: layers of fabric components, illumination system, HVAC system, fire safety system, lift, fire extinguishers and rooms (with correct name, function, number of people, etc.). The model has been made with the help of eng. Hamir Hakim and Roberto Ferrari using Autodesk Revit.

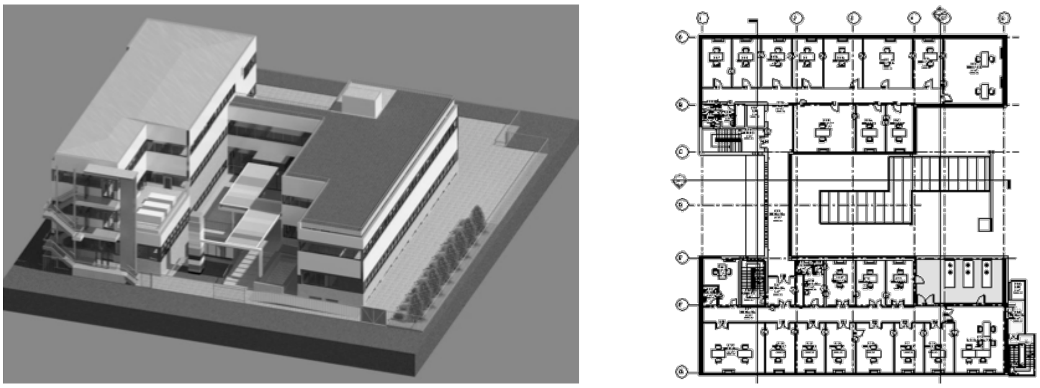

Figure 4: BIM model of the case study (left) and plan of the first floor (right)

The model has been exported from Revit in IFC, allowing to use it in SMC. The coherence of the elements imported in SMC has been checked in the information takeoff section. The requirements have been added to the SMC ruleset, with an explanation and the parameters needed to the check. As said before, it has been possible to add only a part of the requirements (more than 50%) in the ruleset (for the 9 main space categories of the office building), as many requirements were difficult to be managed inside SMC (at least in this first trial). SMC automatically gives a report with the requirements fulfilled or not and the result is that the building presents these issues: some doors (mainly of the rest rooms) have not the minimum width (not for fire safety issues), one door in the under ground opens inside the space and not outside (this issue is related to fire safety) and one office has not the minimum area required (Figure 5).

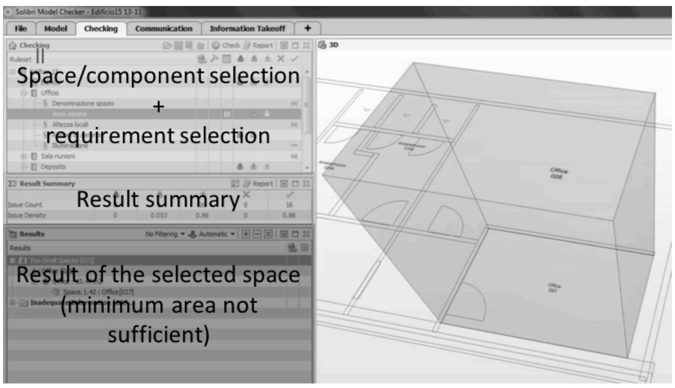

Figure 5: Example of requirement checking in Solibri Model Checker

Some other small issues have been found, e.g. one corridor in the underground has not the minimum width to be considered accessible (but the zone is used as a warehouse at the moment). All the remaining requirements not checked in SMC have been checked within the checking tool, developed in an Excel spreadsheet; among them: permeable surfaces, stairwell typologies, furniture dimensions, finishing fire rating, etc.. Authors are currently working on a way to overcome this issue, so to implement all the requirements (or at least the majority) inside the BIM model, so to fully automate the check. Also the manual checking highlighted some minor noncompliances, among them: some furniture is missing (e.g. dedicated card index cabinets) and there are no data regarding the fire resistance of some finishing (missing data are considered noncompliant). All the results coming from Solibri have been transposed into the Excel checklist (connected to the requirements compliance index of §4), so to calculate the rating associated and to have a complete view of the criticalities encountered. In general, the building has only few minor issues that can be solved without a great effort; the final rating, for both the whole building and spaces is abundantly above sufficiency (no voluntary requirements have been considered in this analysis). As said before, this case study has only the purpose of outlining the procedure and to show the process of regulatory compliance checking.

6. Discussion

The requirements compliance index has been calculated by analysing all the spaces of the buildings and also the building as a whole (distances from other buildings and distances inside the buildings, e.g. from fire exits). The requirements list was exhaustive and comprehended all the issues to be addressed by these types of controls. The BIM model analysed with SMC greatly helped in cutting the working time to analyse geometrical data, while some issues have been encountered with calculated values (e.g. the window/floor surface ratio). All the requirements checked on the BIM model have been transposed in the tool (in Microsoft Excel), so to have the complete view of the building. There is still a great effort to be paid in developing this tool, starting from a precise procedure to be followed to analyse requirements (which need to be checked in the BIM model and which not). In addition to this, the calculation procedure can be changed and improved according further tests on case studies. Nevertheless, this tool can be easily used by both technicians and asset managers (e.g. without engineering skills). The use of a BIM model and of BIM authoring tools is not mandatory to provide a correct assessment of the regulatory compliance. A possible future development of this tool, once fully defined, is to implement it in a web interface, so to be used online, maybe in connection with an external database and/or the BIM model database; using Revit DBlink it is possible to extract and interact with the database of the BIM model under analysis.

7. Conclusions

Eventually, a great effort still needs to be paid to refine this tool, as at the moment it can be considered just an initial work. The first result is the list of requirements, divided by spaces; this can be used to check requirements during design or handover and even (partially) implemented in a rule set of Solibri Model Checker, so to be automatically checked. The calculation procedure should be revised according to the results of the case studies, which are planned to be assessed in a short future. The second step to be done is to associate costs to restore the compliance with the current binding requirements, so to have a clear appraisal of the expenses to be made; the same has been done with another indicator regarding building degradation and ageing, connected to maintenance, repair and replacement costs over the life cycle. BIM technologies, together with a complete and up-to-date requirements database, could lead to important savings, safer buildings and a better management of portfolios, as the knowledge is the basis of a proper management strategy.

CIB World Building Congress 2016

Proceedings of the CIB World Building Congress 2016

These proceedings (Volume I - V) bring together papers presented at the **CIB World Building Congress 2016**. The CIB World Building Congresses have for several decades been the leading global events on construction research and innovation.

The theme for CIB World Building Congress 2016 was "Intelligent built environment for life". It highlights the importance of build environment and its development to the society. This triennial congress focused on the intelligent processes, products and services of construction industry:

- How can research help to improve the contribution of constructed assets to digitalizing world and service needs?
- How will the research community meet emerging new needs of the users?

CIB is an association whose objectives are to stimulate and facilitate international cooperation and information exchange between governmental research institutes in the building and construction sector, with an emphasis on those institutes engaged in technical fields of research. CIB is a world wide network of over 5.000 experts from about 500 member organisations with a research, university, industry or government background, who collectively are active in all aspects of research and innvation for building and construction.

Preface

The aim of this last volume of the CIB World Building Congress (WBC), 2016 *Intelligent built environment for life*, is to explore the various needs of modern construction and offer new ways and techniques to address them. In recent years, stakeholder expectations have led to political, social and economic pressure on the construction industry. Modern buildings are expected to be innovative, sustainable, resilient to hazards and other risks as well as being easy to manage. In addition, clients expect to be part of the decision process to ensure their needs are met and often tied to legal bonds with professionals, a situation that can generate conflicts.

More than 200 authors have contributed to the 98 papers included in this volume. The vast majority of this research work is led by academics (70 papers) who discuss problems from a theoretical background and suggest solutions; whilst the remaining is led by industry researchers (28 papers) who provide an insight on real life through case studies. The present research work is led by researchers in 28 countries representing east and west, north and south of the globe. We hope that product and service enhancement will result from our sharing of information and collective experience.

Papers were classified into seven areas, including:

- Procurement, finance and conflicts (10 papers);
- Stakeholder involvement and satisfaction (12 papers);
- Innovative design and construction (17 papers);
- Risk mitigation, resilience and health and safety (13 papers);
- Sustainable construction (15 papers);
- Building information modelling (BIM) (16 papers); and
- Facilities management (15 papers).

Many lessons could be learned from each area and each research paper. However, one of the key lessons to be learned from this body of international research outputs is the need to better integrate design, construction and post-occupancy management in a construction lifecycle specifically with advancement of technology and availability of BIM tools. The second key lesson is the increasing acknowledgment of resilience and sustainability as a major part of modern construction.

Multi-organizational PMOs for Interface Management between Construction Megaprojects and Its Sociological Context in China

Qiang Mou, Guangshe Jia, Yang Liu, Qinli Huang, Xueying Wang, and Songyu Yan

Department of Construction Management and Real Estate, School of Economics and Management, Tonji University, China

Email: 5ulike@tongji.edu.cn

Abstract

This conceptual paper aims at providing an in-depth understanding of the role of the project management office (PMO) as a coordination mechanism between its complex multi-organizational settings of construction megaprojects and the sociological context in China. In the project practice of some large infrastructure in China, the coexistence of multiple organizational PMOs (with members from several independent organizations) is a common situation to coordinate the interface of sociological context and construction mega-project. The proposed conceptual framework builds on three main foundations: social conflict theory, governance mechanisms, and, the multi-organizational PMO. The proposed methodology is based on in-depth case studies, both of which are airport projects in China. By taking a sociological perspective, this research offers a novel and promising approach to the study of mega-projects and PMOs.

Keywords: Construction Megaprojects, PMO, coordination mechanism, social conflict theory

1. Introduction

The *New York Times* had an article in an early 2015 edition, title: "In China, Projects to Make Great Wall Feel Small."(Barboza, 2015, p. B7). Among others, five major Chinese infrastructure projects were described, each one breaking some of the previous infrastructure limits. For instance, there is the Jiaozhou Bay Bridge, the world's longest sea-crossing bridge at 26.4 miles. These mega-projects are not only about engineering and construction; they are about building a national identity, said Bent Flyvbjerg, as interviewed in this article (Barboza, 2015).

Recent decades have shown a significant increase in the number of mega-projects and their value worldwide (Flyvbjerg, 2014b). In China, as elsewhere, these projects have a major impact on the global economy (Bredillet, Yatim, & Ruiz, 2010). Moreover, this tendency toward mega-projects is expected to continue with an increase in both their number and value (Flyvbjerg, 2014b). However, a worrying aspect of these projects is an extraordinary high level of failing to meet their objectives (among others, Flyvbjerg, 2014b).

Since the birth of project management in the 1950s, construction megaprojects have been a continuous and important object of inquiry, first with military projects, than extending to the construction of buildings, transportation and power systems (Peter W.G. Morris, 2013). Recently, Flyvbjerg edited *Megaproject Planning And Management: Essential Readings,* a collection of about 70 influent articles and book chapters dating from 1951 to 2012 from various contributors in the field (Flyvbjerg, 2014a). The sections of this collection proposed are relevant to understand the current issues and plural views with regards to megaprojects, which are: The History of Megaprojects, Project Post-mortems, Front-end Management, Governance and Institutions, Stakeholder Management, Finance, Delivery, Social and Environmental Impacts, Innovation, and Case Studies. Whereas some themes, related to the technical core of project management (such as planning, control, and engineering complexity) have long been studied in project management, strategic issues in megaprojects have gained more recognition in the past decades (Morris, 2013). For example, the attention of scholars has been oriented towards innovation (Davies, Brady, Prencipe, & Hobday, 2011; Miller &Lessard, 2000), governance regimes and frameworks (Klakegg, Williams, & Magnussen, 2009; Miller & Hobbs, 2005) and quest for success (Klakegg et al., 2009; Samset & Volden, 2013). However, researches on the social environment taken into consideration when studying mega-projects have been scarce, and some scholars have called for research development in that direction (Morris, 2013; Scott, 2012). From a social context perspective, there are numerous stakeholders in these projects. Their coordination and the adaptation of the mega-project to its social context is an important issue to solve.

This paper aims at proposing a conceptual framework for the study of the sociological context of construction mega-projects in China, as well as the role of the inter-organizational PMO as a coordination mechanism. Lessons learned from this research, we believe, will contribute to the theoretical and practical understanding of the management of mega-projects globally.

The following section presents the research background from the literature on three themes: mega-projects, sociological context, and the inter-organizational PMO. Following the literature review is the proposed conceptual framework, and the proposed methodology. The conclusion suggests the contribution of this paper, as well as its limitations and the direction for future research.

2. Research Background

2.1 Mega-projects

Progress in science and technology has spurred the launch of construction mega-projects globally, especially in developing countries such as China. For example, China's high-speed railway project is one of the world's largest mega-projects. However, despite their significant character these mega construction projects also bring great difficulties and challenges to project management (Flyvbjerg, 2004).

Considering the main characteristics of construction mega-projects, they involve a huge number of participants and they have significant social and economic impacts, extensive work loads, large geographical coverage and close connection to other major developments (Mok et al., 2015).

There are also different types of mega-projects, especially in terms of their level of aspiration, lead times, complexity, and stakeholder involvement (Flyvbjerg, 2014a). Construction mega-projects present challenges to project management in their complexity, uncertainty, integrated management, etc. (Sun & Zhang, 2011). Complexities in managing mega construction projects can be viewed from three aspects: technical, social and managerial. Social aspects relate to complexities from the inadvertent impact of mega-projects on the environment and social systems within their location of implementation (Li & Guo, 2011).

The research of mega-projects has reached a new stage in the context of globalization. For example, the IMEC research program on large engineering projects included the benchmark of sixty projects at an international scale to identify best practices (Miller & Lessard, 2000). Results of this influential study have emphasized the central role of project sponsors, who need to 'shape' the front-end of the project as well as institutional arrangements (defined as laws, regulations and agreed to practices) in order to allow flexibility and 'governability' of the project, which are critical for success (Miller & Lessard, 2000). Another global study is that of Merrow (2011), who concludes from the analysis of a dataset of 318 megaprojects from around the world that two thirds are failures, mostly due to endogenous factors. Finally, an important initiative to study megaprojects using a global perspective comes from Scott and his colleagues from the Collaboratory for Research on Global Projects (CRGP) of the Stanford University. In an edited book of 11 chapters, the authors, based predominantly on the 3 pillars of Scott (2008) (regulative, normative and cultural-cognitive), emphasize the importance of an enlarged understanding of the role that both culture and politics play in global projects.

As research has shown that mega-projects are qualitatively more complex and riskier than usual operations and smaller scale projects, they therefore require governance regimes that are different from those of more routine and less risky endeavours (Miller & Hobbs, 2005). Better planning methods and changing governance structures are important to counteract the main problem of misinformation about costs, benefits and risks of mega-projects (Flyvbjerg, 2007).

As other megaprojects around the world, in China, some construction megaprojects also failed to meet their objectives. For example, the PX case in Xiamen, China. The government of Xiamen planned to build the Haicang PX project, which had been agreed by the State Council, Environmental Protection Administration and National Development and Reform Commission. However, once plans were revealed to public, strong oppositions aroused among citizens in Xiamen and even incurred concerns nationwide. The government of Xiamen only focused on the economic benefits of the project before the project announcement while omitting public outreach and public opinion. At last, the government of Xiamen bowed to public opinion and shifted the project to a remote island.

Another example is the Sanmenxia Hydropower Station in China. This project was put into operation without considering the impact of sediment deposition in the Weihe River. The project was cancelled, and resulted in repeated severe flooding (Chen, Le & Ren, 2006).

These failures in meeting project targets were caused by a neglect of the social context of the projects. Increasing complexity of mega construction projects require increased study of their social context. Traditional project management with appropriate method and data cannot meet the needs of mega construction projects (Sun, Zhang, 2011.) The social responsibility activities associated with these projects need to be managed throughout (Salazar et al., 2012), and especially considered through their life-cycle (Zeng et al., 2014). Construction mega-projects have more interactions with the society and require a wider perspective for their study, such that a comprehensive point of view is needed for their study (Mao & Jia, 2011).

Besides its inherent project properties, mega-projects also have social attributes, the dominant feature in social context. The mega-project has close connections with globalization and civilization, but few articles have addressed the social analyses of mega-projects. From a perspective of social conflict theory, there are strong connections between mega-projects and social conflict (Jia et al., 2011). The social attributes of construction mega-projects include four aspects: 1) the construction project is the material basis for human survival; 2) the construction project is a matter of social activities; 3) the process of construction project is that human beings transform the world; and, 4) the construction project is the representative of social culture and civilization (Mao & Jia, 2011). It is adaptation to the social context is the ultimate goal of a construction mega-project (Tian & Chen, 2013).

2.2 PMO and the inter-organizational context

Emergence and deployment of PMOs in organizations followed the increasing use of projects in the innovation and development of economy and societies (Aubry, Hobbs, & Thuillier, 2007). Scholars have shown the wide diversity of the PMO (Hobbs & Aubry, 2010) and the difficulty to classify them empirically (Hobbs & Aubry, 2008), or explain their performance (Hobbs & Aubry, 2011). Their constant transformations have also been the object of research leading to a theoretical approach of an evolutionary process view (Aubry, Müller, Hobbs, & Blomquist, 2010) or other conceptualizations such as emptying process (Pellegrinelli & Garagna, 2009) and sustainability (Hurt & Thomas, 2009). Their role has also been scrutinised in different ways such as deconstructing the PMO to better understand their function (Crawford, 2010), or to critically assess their lack of engagement in integrating organizational change (Artto, Kulvik, Poskela, & Turkulainen, 2011), and acknowledge their impact on the knowledge management in project-based organizations (Pemsel & Wiewiora, 2013).

Most of the research has focus on the entity itself or its transformation process. Few studies have focused on the different roles of PMOs when tightly associated with activities of portfolio management with the exception of Unger and colleagues (2011), who specifically study the role of a portfolio PMO on project and portfolio performance.

In the last 10 years, research on PMOs has provided a good understanding of the phenomenon by looking at the *what* and the *how* its evolution, or in ontological and epistemological words, as a thing and as a process (Van de Ven & Poole, 2005). However, there are limitations to what the research has covered on PMOs, mainly in isolating this entity from the rest of the organization.

To our knowledge, none of the research on PMOs has studied this entity as a governance mechanism and included it within the organizational design (Winch, 2014). This missing link contributes to the difficulty of positioning project management as being part of the organization' strategy, project management being responsible of strategy implementation, and of strategy formulation, at a lesser degree (following, Jacobs, 2010). To engage project management at the strategic and institutional level (Morris & Geraldi, 2011) requires, among others, to study these governance mechanisms embedded in the overall organizational governance.

2.3 Stakeholders in the sociological context

2.3.1 Stakeholder Identification and Classification

Stakeholders include individuals, groups or organizations affected by the project, and can be classified as: beneficiaries, losers and neutral parties (Housing and Urban-Rural Development Department of China, 2014). The stakeholders of construction mega-projects can be divided into eight classifications (Mao & Jia, 2011): the government, investors, owners, contractors, volunteers, departments (e.g., NGO), the public, and other stakeholders. According to a stakeholder party-classification method, illustrated in Table 1, the eight classifications of the stakeholders of construction mega-projects can be divided into four parties: the government, the construction mega-projects, the benefited public, and the impaired (impacted) public.

Table 1 Stakeholder Identification and Classification

Four Parties	The Stakeholders
The Government party	The Planning Bureau
	The Land Bureau
	The Housing and Urban Construction Bureau
The Construction Mega-Projects party	Investors
	Owners
	Contractors
	Sub-contractors
The Benefited Public party	Groups benefited from the project construction
	The other benefited stakeholders
The Impaired (impacted) Public party	Groups impaired by the project construction
	The other impaired stakeholders

2.3.2 The Interactions between Stakeholders

The relationships between different stakeholders and their interactions are dynamic network (Miller and Hobbs, 2005). Through the four roles of different stakeholders in the practice of construction mega-projects, they form a complex interaction in a logical network during the project as shown in Figure 1(Mao & Jia, 2011).

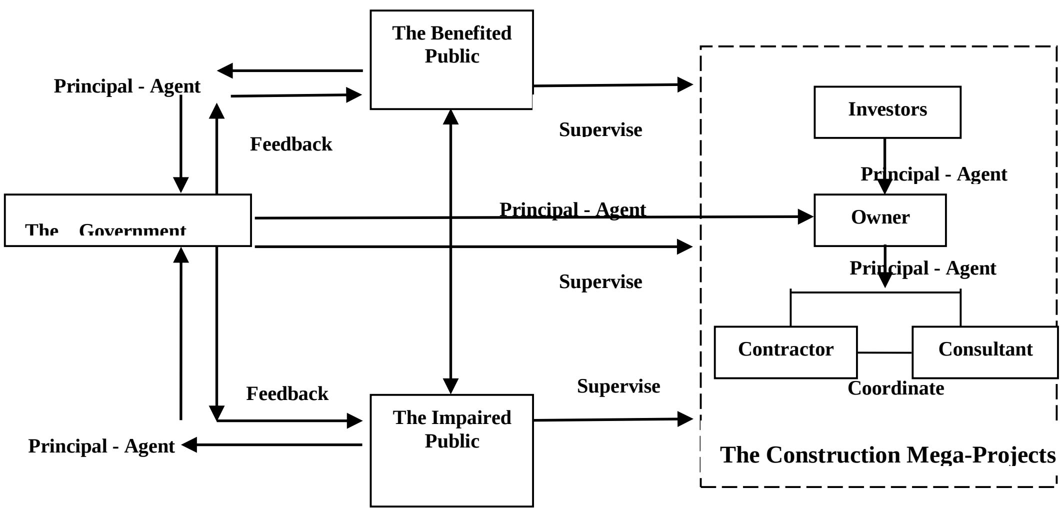

Figure 1 The Interactions between stakeholders of construction mega-projects (Mao & Jia, 2011)

In the study of the interaction between construction mega-projects and its social context, the literature focuses on social evaluation of construction mega-projects (Housing and Urban-Rural Development Department of China, 2014). But there has been problems regarding implementation of the management plan; which is, to mitigate the negative social impact of construction mega-projects. In the actual practice of projects, the establishment of multi-organizational PMOs have been shown to respond to corresponding problems (Headquarters of

Shanghai Hongqiao Integrated Transportation Hub [ITH], 2011). Therefore, we propose the following assumption from organizational perspective.

2.4 Research questions

Building on the review of the literature, the proposed research should investigate:

- The nature of the sociological context of construction mega-projects
- The characteristics of the construction mega-projects under its sociological contexts
- The role of the multi-organizational PMO at the interface of sociological context and construction mega-projects.

From what has been said above, the following research questions have been identified: RQ1: What is the impact of sociological context on the construction mega-projects?

RQ2: What is the role of multi-organizational PMOs in this relationship?

These questions will address the specific coordination tasks of the PMOs in two preliminary stages (Shizhao, 2014) of construction mega-projects: the initial proposal stage and the feasibility stages.

During the initial proposal stage, the main task of the multi-organizational PMOs is to coordinate the project planning and design, identify stakeholders of the construction mega-projects and risks the project may face. During the feasibility studies stage, the main task of the multi-organizational PMOs is to give a comprehensive analysis of the interactions between the various stakeholders and to propose measures to mitigate adverse social impacts on early phase of the construction mega-projects.

The Unit of Analysis is the PMO as a coordination mechanism on multi-organizational settings in public construction mega-projects. The level of analysis spans from the societal via, the organizational to the unit level. Thus, the study follows the suggestions for more multi-level studies (Courgeau & Baccaini, 1998; Baccaini and Courgeau,1998; Rousseau,1985).

3. Conceptual Framework

The proposed conceptual framework brings together three different but complementary theoretical perspectives. Scholars studying phenomena in organization are facing complex situations in pluralist setting (Denis, Langley, & Rouleau, 2007). In their paper, Denis et al. (2007) argue for adopting multiple theoretical perspectives to understand or to explain pluralistic contexts defined as "organizational contexts characterized by three mains features: multiple objectives, diffuse power and knowledge-based work processes." (Denis et al., 2007, p. 179). In their paper, they propose a multifaceted theoretical framework combining three theories from sociology and theory of organization: actor-network theory, convention theory and social practice theory. There is no doubt that mega-project are situations in pluralist context as the three main features can be identified:

- Multiple objectives. In mega-project context, objectives are set by a vast array of stakeholders having different, and sometimes conflicting, expectations as illustrated by Jia and colleagues (2011) in social conflicts.
- Diffuse power. Governance mechanisms generally define the formal power system and the decision making process. In mega-project, the power system is complex having multiple organizations forming a dynamic network of (Klakegg et al., 2009) in which informal power is developed making difficult (or impossible) to make a decision in a unique central locus (Miller & Hobbs, 2005). Moreover, public mega-projects do face particular situations of dual power systems – elective versus administrative. Governance frameworks developed in western world have specifically this role of regulating the power system.
- Knowledge-based work processes. Little is known at early stage of any project. Knowledge develops during the project on *what* to do and *how* to do it (Midler, 1993; Turner & Cochrane, 1993; Winter & Szczepanek, 2009).

The conceptual framework for the study of construction mega-projects in China is built on three major theoretical components: the sociological context, the construction mega-projects, and the multi-organizational PMOs. Altogether, the three components are embedded in each other, forming a coherent model having reflecting the tall ontology proper for the study of pluralism setting (Seidl & Whittington, 2014) (See Figure 2).

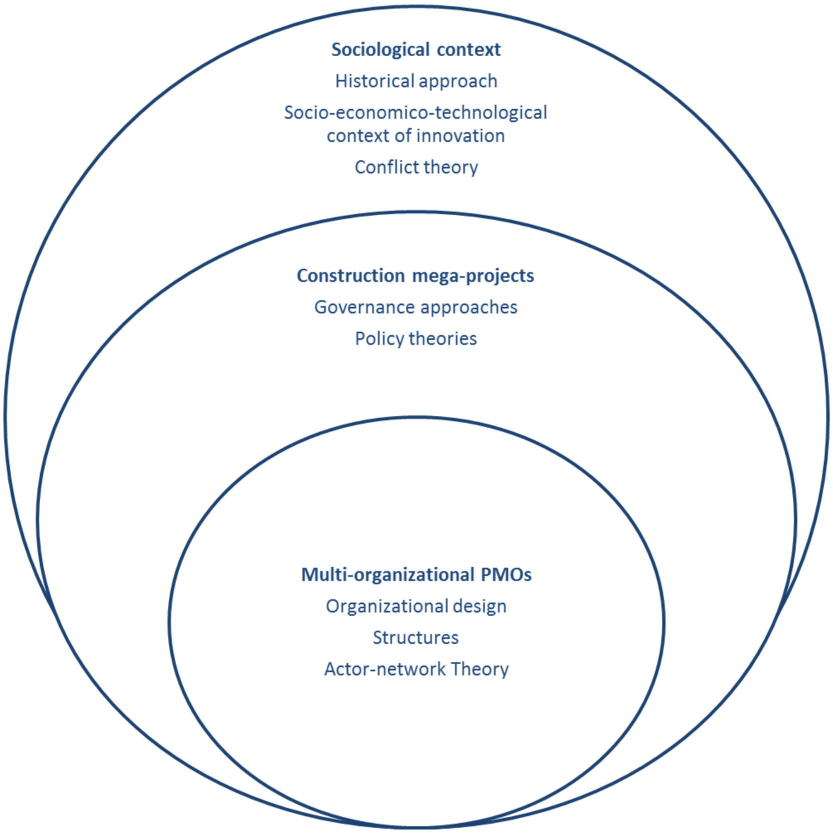

Figure 2 Conceptual Framework

Following Hughes (Hughes, 1987, 1998), innovations are shaped by their socio-technological environment, as they also shape their environment. Not only does innovations happens at a specific point in time, they are the result of the evolution and history of other elements in the environment (Petroski, 1994). For mega-projects, we will take into consideration the context in which this project happens. In some cases, project does have a long history before a decision is made to initiate the project. In social context, we will consider the conflict theory to explore the relationship between different stakeholders where tensions and conflicts are more likely to happen (Aubry, Hobbs, Müller, & Blomquist, 2010). It is very much in line with the call for turning to theories form the sociology of organizations to enlighten project management situations (Floricel, Sergi, Bonneau, & Aubry, 2013).

Mega-projects require that governance arrangements be put in place in order to clarify the formal decision-making process. Decision-making process for mega-project could certainly be looked at throughout economic theory such as transaction-cost theory (Williamson & Masten, 1999) or agency theory (Jensen, 2000). Klakegg and colleagues (2009) have identified some resonance of these perspectives in some aspects such as control, incentive, information, asses specificity, etc. (Klakegg et al., 2009). While these theories would certainly enlighten governance aspects, this research would rather turn to more institutionalism perspective with a sociological and political understanding of governance. In this sense, we adopt the paradigms view on governance where single organization manage different projects under different mix of project output (behaviour or outcomes) and project orientation (shareholder or stakeholder) (Müller, 2011). In this context, governance frameworks are good artefacts to understand the governance regime in which those construction mega-projects are executed (Klakegg et al., 2009).

Then, the multi-organizational PMO has to be understood in different aspects. A first aspect refers to the process of organizational for projects. In this aspect, we will base our work on the work of Miller (Chen & Miller, 2010; Greenwood & Miller, 2010; Miller, 2005). We will also work with the three domains identified by Winch (2014) specific to the field of project management. Description of the PMO formal structure will be done using the model developed by Hobbs and Aubry (Hobbs & Aubry, 2010). The structure will also be explored through actor network theory (ANT) to take into account the construction of the network around a certain number of artefacts, one of which being the governance framework. ANT provides a dynamic view connecting actors and non-human actants together in building and maintaining some controversies (Aubry, 2011).

4. Methodology

We develop the study's methodology following the approach of Saunders, Lewis and Thornhill (2007) by starting with the philosophical perspective, then determine the inductive, deductive or abductive approach, followed by the research strategy and the time (cross sectional or longitudinal) and methods (mono, multi or mixed method) approach, and finally determine the type of data to be collected.

A study with the indicated scope and level of analysis requires a comprehensive underlying ontology that allows for the integration of subjective societal and organizational worldviews with more objective worldviews of planning, control and coordination in projects. Therefore we take a critical realist perspective (Bhaskar, 2008). This ontology is based on three layers, namely mechanisms, events, and experiences. This ontological approach is to be put in relation with Seidl and Whittington (2014) call for adopting taller ontology aiming at expressing the organizational context in more precise terms. Here the lowest level, named *mechanisms*, represents the underlying generalizable laws or the assumptions thereof, such as those of objective planning of projects, measurable benefits of projects etc. These mechanisms give rise to the second layer, *events*. Enabled through the mechanisms, events constitute both objective and subjective representations, such as mega-projects' final products and the use of them. These events (of usage) give rise to the top layer, *experience*. This is the most subjective layer and represents the idiosyncratic experience of individuals, contingent on the events, which, again, are contingent on the underlying mechanisms. Critical realism integrates these three layers of worldviews into a single research perspective (Archer, Bhaskar, Collier, Lawson, & Norrie, 1998; Bhaskar, 1975).

To leverage existing theories for the ‘sense making’ of the data collected in the study we use an abductive approach in the sense of Alvesson and Sköldberg (2009).This approach allows for going back and forth between existing theories, collected empirical evidence, and the experience of the researchers in order to make sense of yet non-understood phenomena.

Four in-depth case studies in the sense of Yin (2009) will be done, using ‘maximum variation’ sampling to allow for broadest understanding of the phenomenon. In addition we prefer this approach over a quantitative study because of potential problems in achieving a sufficient sample size when concentrating on public construction mega-projects only (Müller, Pemsel, & Shao, 2014).

At first place, search for public documents will take place to acknowledge the media communications and their possible effects on project team. Research design will provide opportunities to capture data at different levels and from a variety of actors, as described in our conceptual framework. Data collection strategy will include semi-structured interviews with 20-30 actors for each project. Each interview will last an average of an hour and will be transcribe in Word files and then analyzed using Atlas.ti (ATLAS.ti Software Development, 2004). When possible, observations on site will take place. This will provide data on the practices in each site. Field notes will be taken and processed based on as ethnographical techniques. This should provide a good understanding of each sociological context of the projects. Documents and other artefacts on the projects or on the organizations will be collected and analyzed to provide information on the socio-politico-technological context of the project.

Different strategies will be used for data analysis following Langley (1999). Among others, grounded theory will serve as a strong inductive approach to listen to what the interviewees will have to say, graphical views will provide visual setting that is helpful in clarifying concepts, and some quantitative analysis may be possible in counting different activities or facts. In combination to these strategies, related data analysis techniques will follow the suggestion by Miles & Huberman (1994) to help make sense of large quality of data.

Validity will be ensured using the suggestions by Yin (2009). For that we do within-case and across case analysis, look for convergence and cross validation of the collected data, best possible respondents, and use theoretical saturation for interviewee sampling. Reliability will be assured through the development of a case study protocol and its usage throughout the study.

5. Discussion and Conclusion

This paper addresses problematics related to the management of megaprojects. Challenges in this field are crucial as megaprojects in general are often associated with failures in one hand, and on the other hand, the tendency is going towards more and larger megaprojects (Flyvbjerg, 2014b). Megaprojects have been defined as pluralistic contexts (Denis et al., 2007). Based on a review of the literature, this paper proposes a conceptual framework combining three layers of theoretical approaches to capture in an integrative way the pluralism setting of construction megaprojects. This conceptual framework is intended to drive a wide research taking place in China (Chen & Miller, 2010).

Novelty of this research bears on two main elements. First, as of now, the sociological aspects of megaprojects have been neglected in the research on megaprojects. This research aims at including social context and more particularly, social conflicts among stakeholders as key elements of the environment. In doing so, the context is becoming personified instead of being a grey undefined area (Seidl & Whittington, 2014). Second, the PMO is deliberately interpreted as a governance mechanism which is worth to be considered within the organizational design for projects.

There can be many perspectives to study the management of mega-projects, but from the perspective of sociology and PMO is promising. This article mix sociology and PMO to study the impact of sociological context on the construction mega-projects and the role of PMO as a coordination mechanism and give a conceptual framework which put mega-project in the social context and use PMO to coordinate them.

This paper is conceptual. This raises a first limitation as no empirical evidence comes to validate our conceptual approach. However, this is a first step for a larger research to be undertaken in the following months. A second limitation is associated with the conceptual approach based on multi facet theories. While this approach fits well pluralistic contexts (Denis et al., 2007), it may cause the analysis to stay at higher level of interpretation instead of going in depth in one single theory. Impact of this would be the incapacity to provide new theoretical insights. Globally, we think that this conceptual framework is promising for many other researches in the field of megaprojects.

A Traditional, Large Engineering Service Adopts the Best Value Approach

Sicco Santema[1], Elske Bosma[2], Dean Kashiwagi[3] and Isaac Kashiwagi[1]

Email: santema@scenter.nl

Abstract

The BV environment was introduced into the Netherlands in 2006. By 2008 testing was being done by a partnership of Arizona State University and Scenter [Sicco Santema, professor from Delft University]. In 2010, the $1B fast track projects were procured by the Rijkswaterstaat, and by 2012, the BV approach had become the "buzzword" of procurement. However, in the delivery of professional engineering services, larger, more traditional services which were built on a system of relationships between clients and vendors, MDC from the clients' experts, and the importance of "billable man-hours", the transition from a traditional approach to a best value approach is very challenging. Large traditional professional organizations naturally will have more difficulty adapting to the new approach. The BV approach utilized the expertise of experts to replace the need for relationships and owner management, direction and control [MDC.] It also places less value on traditional practices that have been used by professional services to get business [relationships and working together with the client in a trust based relationship]. The study captures the efforts of a very successful engineering firm [the largest in the Netherlands] as they attempt to become successful in this new approach. The best value team that they have put together has had outstanding results in using the BV approach to changing their paradigm.

Keywords: professional services, best value, Netherlands, Royal Haskoning DHV, delivery of services

1. Introduction to the Selection of Design Services

Professional services were always selected differently from other construction services. They were identified as professional services which used engineering principles to solve and provide solutions to owner requirements. They developed a selection system called Qualification Based System or QBS, which selected designers based on the professional's past performance, professional licenses, professional relationships and technical knowledge in the firm (Child, Sullivan & Kashiwagi, 2010; D. Kashiwagi, J. Kashiwagi & Child, 2014). The QBS system resulted in a system where the owner's selected the professional firm based on relationships, marketing brochures and firms' reputations. The selection process resulted in client's selection boards deciding who was the best qualified. In many government environment's, price was not a selection criteria. After the QBS was performed, a professional service is selected and price is negotiated. Oftentimes, it is a fixed percentage of the construction cost, and not what the actual professional services would cost.

The QBS and other similar selection systems resulted in professional services having the following practices (Child, Sullivan & Kashiwagi, 2010; D. Kashiwagi, J. Kashiwagi & Child, 2014; Sullivan & Michael, 2011):

1. Depending on marketing and relationships to get their work.
2. Professional services becoming more reactive to the clients' needs.
3. Strong relationships become the solution for engineering and design issues.
4. Design schedules becoming less important leading to design change orders and redesigns.
5. Large design services becoming more fixated on maintaining "billable man-hours" than utilizing their expertise.
6. More administrative and meeting duties than utilizing technical expertise.
7. A void of project management skills which concentrated on profit margin, efficiency, effectiveness and maximizing profit/return to the company.

These practices led to the following results (Egan, 1998; FMI / CMAA, 2004; FMI / CMAA, 2010; Sullivan & Michael, 2011; Tucker, 2003):

1. Poor customer satisfaction.
2. Clients reviewing the professional's work, and managing, directing and controlling the professional services.
3. The owners/clients' had a poor perception of designers and engineer's capability, quality of work and professionalism.
4. An inability in a large design firm to identify the expert, select the expert for a project and allow the expert to plan the project from the beginning to the end [utilizing their expertise to estimate quantities and identify the risk that other stakeholders bring to the design project and mitigating the risk by creating transparency and through a risk mitigation plan].
5. Work was procured through a marketing/relationship process called the Qualification Based System or QBS. The selection of the firm is done through an owner's selection board that decides who is the best qualified, then negotiates a contract with the selected vendor.

These design practices are in all countries and cultures [underdeveloped, developing and developed countries]. The authors have been in Africa, Malaysia, China, U.S. and Europe in which the practices are observed to be the same.

The Best Value approach has been in the Netherlands since 2007. The Rijkswaterstaat [tasked with maintaining roads and waterways in the Netherlands] delivered the "fast track projects" using the Best Value approach [known as best value procurement or BVP]. The following results were realized (Van de Rijt, Witteveen, Vis & Santema, 2011):

1. Procurement transactions and costs were minimized by 50%.
2. Construction time was minimized by an average of 25%

3. 95% of all project cost and time deviations were caused by the owner/client and their professional services.

Professional services were also procured by the BVP approach. Immediately the following problems were realized (J. Kashiwagi, Sullivan & D. Kashiwagi, 2009; Kashiwagi, 2014b):

1. The design professionals were reactive and not used to being accountable to setting a plan, identifying the deliverable to be delivered, making the assumptions that should be made utilizing their expertise, and having a risk mitigation plan that minimized the risk that they did not control.
2. The owner/client's project managers were confused and thought that the clarification period was a time to make the contractors do work to identify all the unknowns.
3. The design services faced the challenge of how to identify and utilize expertise in their own organizations.
4. Large design organizations were confused how to match their need to transform their approach from concentrating on "billable hours" to utilizing expertise.

The Performance Based Studies Research Group (PBSRG) identified the following about the Dutch Best Value movement:

1. Per capita, it was the most progressive best value (BV) effort in the world, with most number of certified experts, the largest number of BV technology licenses, more major government clients involved in best value tests and the only country where the professional procurement group [NEVI] and the professional group [RISNET], which includes the professional organization of the design firms, are all licensed in the BV technology from Arizona State University (ASU) and their technology licensing group AZTECH (PBSRG, 2012).
2. BV consulting groups proliferating the BV practices including Scenter [led by Sicco Santema, the best value visionary of the Netherlands], NEVI [3rd largest professional procurement organization in the world], Best Value Europe [organization committed to spread BV throughout Europe] and the Dutch Professional Engineering Organization which is a member of the European Professional Engineering Organization (Kashiwagi, 2014b).
3. The largest government organizations in the Netherlands were participating with the BV effort including Rijkswaterstaat, ProRail, Netherland Rail Service, waterboards, and major cities such as Rotterdam, Amsterdam, Utrecht, and Groningen (Kashiwagi, 2014b; Van de Rijt & Santema, 2013).

2. Problem: How to Transform Professional Services to a Performing Industry

For the BV effort to be sustainable, PBSRG was interested in three major areas: professional services, medical services and IT or ICT services. Professional service was a primary target because the traditional delivery of the professional services was an area where (Child, Sullivan & Kashiwagi, 2010; D. Kashiwagi, J. Kashiwagi & Child, 2014; Egan, 1998; FMI / CMAA, 2004; FMI / CMAA, 2010; Sullivan & Michael, 2011; Tucker, 2003):

1. Management, direction and control was being utilized to minimize risk.
2. It is a commodity area that was being differentiated based on relationships.
3. The professional services had a very poor customer satisfaction rating.

4. The professionals are the first to touch the delivery of construction services and were identified in the Netherlands billion-dollar infrastructure project as the source of 90% of the project cost and time deviations (Van de Rijt & Santema, 2012).
5. In PBSRG construction project tests, the design services and the owner's decision making was the largest source of project cost and time deviations. The owner's representatives and the design services were indistinguishable. They were one entity and the largest problem in the delivery of construction services (J. Kashiwagi, Sullivan & D. Kashiwagi, 2009; Kashiwagi, 2014).

To have a larger and more sustainable impact on the performance of professional services, PBSRG searched for visionaries in one of the more traditional larger professional services companies.

3. Methodology

3.1 Approach

The research approach was simple:
1. Identify one of the largest professional services company.
2. Identify if there were visionaries who understood the BV approach in the company.
3. Identify the strategic plan to transform the large organization into an organization that could utilize the BV approach to increase efficiency, effectiveness and margin/profit for their organization.

3.2 Research

PBSRG set on the following plan to meet the research objectives:
1. Present to all the large professional organizations.
2. Identify one of the organizations who had visionaries.
3. Educate and train the visionaries in the best value approach.
4. Identify if they could follow the BV approach to give their organization the ability to utilize the best value approach.
5. Convince the core group to utilize metrics.
6. Identify if the metrics can be refined to increase the support of the rest of the organization.
7. Pick a case study which shows the success of the BV approach.

4. History of BV with Professional Engineering Groups

From 2011 – 2012, PBSRG started to brief professional engineering firms. The Dutch professional engineering group [under RISNET [Dutch risk management professional group]]. In 2014 RISNET licensed the BV approach technology from ASU, and the Dutch professional engineering group is a subset of RISNET, giving access to all the training material to the engineering group. The Dutch professional engineering group under the leadership of Paul Oortwijn, started presenting the BV approach at the European Engineering Association in 2013, resulting in interest from Norway and Poland. Partnering with the Scenter group [private group which partnered with PBSRG to bring the BV effort into the Netherlands], the Dutch Best Value Procurement (BVP) book is being translated into both Norwegian and Polish languages, with the Polish book to be introduced to the Polish professional engineering group in March 2016.

In 2012, PBSRG was contacted by the second largest engineering and design firm in the Netherlands, Royal Haskoning DHV. Royal Haskoning DHV is an independent, international engineering and project management consultancy with over 130 years of experience. Our professionals deliver services in the fields of aviation, buildings, energy, industry, infrastructure, maritime, mining, transport, urban and rural planning and water. Backed by expertise and experience of nearly 7,000 colleagues across the world, they work for public and private clients in more than 130 countries on five different continents (Royal Haskoning DHV, 2014). A visionary, Elske Bosma, in the company reached out to PBSRG for some guidance, and PBSRG started a relationship to assist them become a best value expert.

4.1 Development of the RHDHV Best Value Effort

PBSRG had already researched how to transform a large organization to have the capability of providing the best value. It had to take the following approach and assumptions:

1. There is no controlling any individuals in the company to change their conceptual thinking by management, direction or control (MDC) or influence.
2. To expect anyone to change was to increase risk.
3. Visionaries had to be identified by their affinity to the concepts of Best Value (BV) and Information Measurement Theory (IMT) which include logic, consistency, leadership characteristics and proactive motivation to make things better.
4. The group should start small.
5. Education is very important to identify more visionaries.
6. People in the organization who do not understand BV, are focusing on amount of work or turnover and profit margin.
7. The BV core group will have to develop metrics that minimize decision making of the organization as soon as possible.
8. The BV group must have a mentor.

The following is a historical account of dates and activities of the development of the RHDHV best value effort led by Elske Bosma, Marcus van der Ven and Oscar Kerkhoven (E. Bosma, Personal Communication, December 9, 2015):

1. April 2012: Elske Bosma starts a BVP network within DHV
2. June 2012: Elske meets Marcus van der Ven, Oscar Kerkhoven and Fred Haarman, who gained experience with BV at Royal Haskoning DHV. They start with the effort to improve the Best Value tender success rate within the new company RHDHV. This was the start of the Best Value core team.
3. September 2013: The BV core team meets with Dean Kashiwagi. The BV core team also brings 2 colleagues of the higher management of RHDHV. Dean is very much interested in the BV effort of the core team.
4. December 2013: The BV core team presents their strategic plan to the executive board of RHDHV. The board approves the plan. A member of the execute board becomes the sponsor of the BV core team.
5. January 2014: Marcus, Oscar and Peter Edward attend the BV Conference in Phoenix, Arizona

6. May 2014: Dean visits the RHDHV's head office in Amersfoort. Over 100 employees of RHDHV attend his presentation and/or the workshops.
7. October 2014: Marcus obtains the A+ certification [Highest BV certification]
8. November 2014: The BV core team starts to give the 2.5-day Best Value course to educate colleagues for the B-certification [Entry level certification]
9. January 2015: The BV core team and 5 other colleagues attend the BV Conference in Phoenix, Arizona
10. June 2015: Dean visits the RHDHV head office in Amersfoort. Appr. 80 persons of RHDHV attend his presentation and/or the workshops.
11. October 2015: Oscar obtains the A+ certification.
12. October 2015: BV team expands group with 3 more persons [One of the three is in the higher management of RHDHV]. Of the BV core team 6 persons of RHDHV will attend the Best Value Conference in Arizona in January 2016.
13. December 2015: The core team has educated over 50 colleagues (B- certification) in 2014/2015.

4.2 RHDV Metrics

One of the objectives of the BV approach is to use metrics to minimize decision making inside and outside of the organization. The BV core team had the following objectives (Royal Haskoning DHV, 2015):

1. Show increased value of the core team activities.
2. Show that if the BV approach and the BV core team was utilized, the amount of work acquired and the success rate should increase. When the numbers become dominant enough, policies will be set by the company that help the non-BV experts to utilize the BV core team.

Table 1 shows the core teams' metrics. Table 2 then shows the metrics that minimize decision making, and will lead to changing RHDHV policies. The RHDV core team also identified a BV expert who began keeping metrics on his procurement projects [Table 3]. PBSRG will continue to work with RHDHV and the engineering consulting professional groups in the Netherlands, Norway and Poland to assist the industry to transform itself into a best value industry.

Table 1: Royal Haskoning DHV Performance Metrics to Minimize Decision Making

Performance Criteria	*2015*
# years BV core team	*3+*
# BV procurement as client PM	*12*
# BV tenders for engineering consultancy projects	*24*
# won	*11 (46%)*
# BV tenders in consortium for construction projects	*13*
# won	*2 (15%)*
# BV interview training key personnel	*50+*
# BV procurement educations	*20+*

# BV presentations	*50+*
# BV knowledge meetings	*10+*
# BV presentation for higher management	*3*
# A+ Certifications	*1*
# B+ Certifications	*8*

(Royal Haskoning DHV (2015) Best Value Performance Metrics. Unpublished raw data.)

Table 2: Royal Haskoning DHV Performance Metrics

Performance Criteria	*BV Support*	*No BV Support*
# of Tenders	*14*	*24*
Tenders Won	*7 (43%)*	*6 (29%)*
Scored 1st or 2nd in PC Submittals	*13 (93%)*	*14 (58%)*
Risk Assessment Score	*5.8*	*5.3*
Value Added Score	*6.2*	*6.1*
Level of Expertise	*7*	*5.8*
Interview	*7.4*	*6.5*

(Royal Haskoning DHV (2015) Best Value Performance Metrics. Unpublished raw data.)

Table 3: Individuals Performance Metrics on Procure Company Projects

Project	*Budget (M euro)*	*Contract value (M euro)*	*Progress*	*Time deviation*	*Cost deviation*	*Client Satisfaction*
Pumping Station Schore	*2.6*	*2.4*	*60%*	*0%*	*0.4%*	*8.4*

Total:	*7.00*	*6.30*				

(Royal Haskoning DHV (2015) Best Value Performance Metrics. Unpublished raw data.)

5. Conclusion

The professional engineering organization in the Netherlands has been proliferating the Best Value approach and the Information Measurement Theory (IMT) concepts. They have been successful in moving the technology into Norway and Poland. PBSRG has identified and is mentoring the second largest engineering firm in the Netherlands, RHDHV into increasing its BV capability and utilizing metrics to minimize the decision making in their organization.

The following have been successfully achieved in this case study research which uses mixed methods to verify the changes. The results include:

1. Selected Royal Haskoning DHV as the large engineering service.

2. RHDHV selected a core team.
3. Core team educated their organization and used metrics to show their activity.
4. Core team refined their metrics to show their organization that the core team should be utilized to increase their competitiveness on potential projects.
5. Identified a BV expert to run BV projects. The BV projects were extremely successful.

The RHDHV organization has BV capability. They will become more competitive and successful as they continue to change their paradigm. Their case study shows that a large organization whose traditional paradigm do not match the BV approach, have the capability to transform itself into the BV paradigm. Their success ensures that the Dutch BV effort will be more sustainable.

Experience with the Use of Building Commissioning Advisor - from Design to Operation

Marianne Forman
Danish Building Research Institute, Aalborg University, Denmark
maf@sbi.aau.dk

Abstract

The increased focus on building energy performance has intensified the need to ensure consistency between energy requirements, design, construction processes and operation in construction projects. With the introduction of the new Danish DS 3090 standard, "The commissioning process in buildings - installations services in new buildings and major renovations" it is expected that this consistency can be ensured. Building Commissioning is a comprehensive quality-assurance process that can be used to ensure and document that a building's systems and installations are designed, installed and tested to comply with the client's requirements. However, experience and knowledge of the impact of the commissioning process on the construction process and the building's performance in practice is still insufficient.

In order to shed light on the role of energy commissioning in construction and on how well it functions, this paper report from the design phase of a large municipal school project in Copenhagen. This project has strict requirements for the building's energy performance, as previous municipal projects have realized a large gap between the calculated energy consumption in the design phase and the actual energy consumption in operation. Hence, Copenhagen Property has chosen to test whether the use of a commissioning adviser can contribute to a process that ensures that operation and use of the building is already mainstreamed in the design stage of the building's technical systems.

The method in the research project is explorative, which means that focus is on the specific use of commissioning in order to learn from the experience and translate it according to Copenhagen Property's long-term strategies, including the need to establish a new internal infrastructure between operations, planning and construction. Drawing on ethnographic methods and theories, this paper will analyse and discuss what the use of a commissioning adviser in the design stage means for the interaction between design and operation. It may seem that "technical solutions" are made before “ongoing learning processes” in which new themes are articulated and understood across the different knowledge boundaries. Since there is a tendency for "technical solutions" to remain after a project, it seems that a solution strategy to develop standards and new consulting services could lead to increased fragmentation of construction projects.

Keywords: Commissioning, construction project, property management, design phase

1. Introduction

There has been increased focus on commissioning in Denmark in the wake of the increased complexity of the buildings' technical systems. At the same time, more advisers have started offering commissioning as a consultancy service to their clients. In 2013 the Industry Initiative Value-Added Construction-process published instructions on the commissioning process, and in 2014 the new Danish standard, DS 3090, "The commissioning process in buildings - installations services in new buildings and major renovations" was published. In the standard, a commissioning process is described as follows:

"*The commissioning process for a building is a quality-assurance process that is performed to obtain, verify and document that a building's technical facilities, installations and systems are planned, designed, installed and tested, and that they are operated and maintained so that they meet the requirements for the total economy of the building, requirements in building regulations and other legislation as well as the client's clearly defined requirements.*" (DS 3090, 2014).

Therefore, there are many expectations to what commissioning can add to the construction sector. Furthermore, there is ongoing debate as to whether commissioning should be introduced as a legal requirement for large buildings.

From the client side, several large property managers have started to develop ways to make performance requirements for building projects. However, R. O. Agustsson and P.A. Jensen indicate that even if commissioning is gaining momentum in Denmark, there is still a long way to go before it is common practice in construction. They also point out that high performance is not guaranteed throughout the life of a building, even if it is high in the beginning of the operating period. To maintain high performance, it is also necessary that the staff is able to operate and maintain the building systems.

Knowledge transfer between construction projects and operations departments is not a new area, either in practice or in research. However the new focus is on buildings' technical systems. In connection with the integration of facility management (FM) knowledge in the design process, Per Anker Jensen argues that the challenge of integrating FM in the design process is the transfer of knowledge. He points to four mechanisms that are in play in the transfer of knowledge:

- *"Codification of knowledge from building operation, which can increase the awareness among designers.*
- *Competences among facilities managers, which can increase the awareness among designers.*
- *Power to ensure that designers take considerations for building operation seriously by using the competences of facilities managers.*
- *Power to ensure that codified knowledge from building operation is used by the design team." (*Jensen, P.A.; 2009 p. 131-132*).*

P.A. Jensen points out that there are several ways to integrate operations considerations into the design phase, including direct involvement of FM managers, the use of specialist consultants and/or specialists from FM providers. He argues that continuous involvement of FM in a building project is best placed in the FM function which will subsequently be responsible for the building, as they need to know the building and can influence building design on the basis of their knowledge of the client organization and end-users (Jensen, P.A. 2009).

Coordination of knowledge in heterogeneous networks in emerging areas in construction

In construction projects, there is a need to coordinate knowledge across many different professions. Commissioning is presented as a quality-assurance system that can help to ensure that the building's engineering and installations work in operation, after the building has been handed over, but what is commissioning?

Integration of information across different professions, professional groups and users in relation to new priorities is thus not only about how data and information flow between the various actors. It is also about the various actors' opportunities to use the information locally in a meaningful way, i.e. as a basis for architects and engineers in the design process and as a basis for operations departments to formulate their requirements for operation in construction projects. In Denmark, new priorities in construction, in this case an initiative concerning the energy performance of buildings, are often followed up by new standards, which include new types of consultant services and coordination-tools. Drawing on ethnographic methods and theories, this paper will analyse and discuss what the use of a commissioning adviser in the design stage means for the interaction between design and operation. The theory of boundary objects in particular is used to analyse the ways in which commissioning supports the need for knowledge sharing across the construction project and the operations department. This approach has been chosen to enhance the analysis of information integration as a knowledge-sharing process across knowledge boundaries. The different objects are characterized according to the typology of Star and Griesemer (1989) and Star (1999, 2010). Each of these boundary objects has different structures that allow them to coordinate knowledge sharing in different ways across communities. Star and Griesemer (1989) have developed four different types of boundary objects from their empirical analysis. They are:

Repositories: "*These are ordered piles of objects which are indexed in a standardized fashion*" (Star and Griesmer, 1998 p 410), (e.g. a library or museum). Individual can use or borrow from the pile for their own purpose. They do not need to negotiate difference in purpose.

Ideal types: "*This is an object such as a diagram, atlas or other description which in fact does not accurately describe the details of any one locality or thing. It is abstracted from all domains, and may be fairly vague. However it is adaptable to a local site precisely because it is fairly vague*" (Star and Griesmer, 1998 p 410).

Coincident boundaries: "*These are common objects which have the same boundaries but different internal contents*" (Star and Griesmer, 1998 p 410), (e.g. a map). "*Work in different sites and with different perspectives can be conducted autonomously, while cooperating parties share a common referent"* (Star and Griesmer, 1998 p 411)

Standardized forms: *"These are boundary object devised as methods of common communication across dispersed work groups"* (Star and Griesmer, 1998 p. 411). *"The advantages of such objects are that local uncertainties are deleted"* (Star and Griesmer, 1998 p 411).

The key objects that are described in the commissioning standard are: Cx meetings, Cx log, and Cx scrutiny. In the case study, the different elements are described with regard to whether they act as boundary objects across the communities. In the case described in this paper, the essential knowledge boundaries that the objects operate in are defined as being between client, energy consultant, operation-team, and Cx adviser. Since the focus is on the design-phase technology, suppliers and contractors are not currently involved. Each community is described with respect to how knowledge is localized, embedded and invested (Carlile, 2002). The way the different communities at micro level use the different objects depends on how the various objects are able to transfer, translate or transform information across the knowledge boundaries, as well as the various communities' ability to use the information in a meaningful way locally. Carlile (2002) has found that knowledge needs to be transformed between knowledge boundaries in connection with product development. It is not enough to transfer or translate information across knowledge boundaries. In this case, it is not a product-development process, but establishment of a new infrastructure across different knowledge boundaries to handle new requirements, and therefore it can be perceived as a parallel to a product-development process. The analysis highlights how the communities relate to the different objects and the importance of the information integration.

2. Research setting and methods

2.1 Setting

The case is from the design phase of a large municipal school project in Copenhagen. The aim of the project was two-fold: to build a new school that meets the requirements for building energy performance, both in the project phase (designed / intended) and operational phase (the actual use), and to test commissioning as a method to obtain the objective. The central actors in the construction project in question were the City of Copenhagen, a Danish architectural firm, a Danish energy engineering company, and an engineering company functioning as client adviser on the project, including the commissioning adviser function. The original purpose was to examine the possibilities for commissioning in the construction industry. Since only a limited number of studies with this focus have been reported, an inductive, qualitative approach based on an in-depth analysis of the case was chosen.

Two social factors played a significant role in the project's genesis. In 2006, the Danish Building Regulations (BR06) introduced a new requirement for the energy performance of buildings based on energy frames, which represents a shift from descriptive regulation to performance-based regulation. The use of energy frames as the main requirements of new construction was a result of the EU Directive on Energy Performance of Buildings. With the shift from descriptive to performance-based regulation of energy requirements for buildings, the need arose for new energy solutions in the construction industry. This increased focus on, and requirements for, the energy performance of buildings challenged both traditional project-organized companies and large operating departments. The need for information integration across construction projects and large operating departments in order to handle these challenges is not only about sharing new types of information across actors. It is also about developing new relationships between practices of information integration within a project setting and an operations department setting, respectively. Vertically within the project, there is a need to develop and articulate the client's technical requirements so that the technical requirements can be input to the design team in the design-process. This is a knowledge-sharing process across architects, engineers and operation teams in construction projects. Longitudinally across portfolios of buildings in major operating departments, there is a need to integrate operational experience with technical systems as a platform for articulating technical requirements for new buildings and to qualify operational departments for performance-based operation.

In 2014, the new Danish Commissioning standard was released and introduced as a way to handle information integration across the construction project and the client. This raises the question of the impact of the standard on the knowledge transfer between the construction project and the operational department.

In connection with the construction of schools in The City of Copenhagen, three units are relevant:

1. Children and Youth Administration, which handles the ordering function of the school and is responsible for user involvement.
2. Construction Copenhagen is the client organization of Copenhagen Municipality and is responsible for carrying out construction of the school.
3. Copenhagen Property, which manages and services the properties owned by the City of Copenhagen and is subsequently responsible for operation of the school.

Copenhagen wants to be CO2-neutral in 2025, which places special demands on the energy performance of municipal buildings. Much experience indicates that today there is often a gap between the designed - and hence projected energy consumption - and the actual energy consumption of buildings, which means that it can be difficult to achieve the desired CO2 reductions. To meet these challenges, in the recent years Copenhagen Property has among other things:

- Reorganized and strengthened the energy operational organization
- Initiated the From Build to Operation (BtD) project to support the interplay between Copenhagen Construction and Copenhagen Property with special focus on early involvement of operational experience and requirements in the design phase of

construction projects. At the beginning of the school project, Copenhagen Construction was part of Copenhagen Property, but was later demerged as a separate unit.

- Increased focus on data and data systems, including facility management systems

In connection with the construction of the new school, the municipality has entered into a contract with a commissioning adviser (Cx adviser). In this connection it is Copenhagen Property's intention to put a clear focus on the energy consumption of the new building and its optimum operating options. The Cx adviser has to coordinate incoming client data regarding requirements for technical facilities and follow-up on meeting these. The contract refers to the standard "commissioning process for buildings - installations in new construction and major renovations", but the consultant services have been adapted to the needs of Copenhagen Property. This means that it is intended that the roles of the Cx adviser is to support increased contact and dialogue between Copenhagen Property and Copenhagen Construction.

2.2 Data

With respect to the qualitative approach, data is collected through observations, qualitative interviews and building case documentation. The construction project was followed in the period 2014 - 2015, when the school was designed. The design process was divided into four phases: program, outline, project and main project. At each stage, the client adviser completed a review of the project documents. The commissioning-function was handled by the client adviser and therefore scrutiny in connection with the commissioning process has been coordinated with the cross-scrutiny process. Since focus is on commissioning, Cx meetings in particular have been observed continuously throughout the design period. In addition, special working meetings occasioned by the commissioning process have been followed. In connection with the observations, it was noted, 1) which actors use the various potential boundary objects and what they use the objects for, and 2) the themes brought up at the meetings and the decisions that were taken. In addition, all documents and minutes of meetings were collected. In the study, the research team had access to the project web, meaning that all documents from the project have been available, including basis, prepared project proposals and all examination reports.

Qualitative interviews were conducted with the client, the Cx adviser, the architect, the energy consultant responsible for the design of all the technical facilities, the operation coordinator and the operation officer working with energy systems, and finally an employee from the department that ordered the school. All interviews were of one-hour duration. The interviews were conducted as a semi-structured interviews, in which the central themes were: local work-tasks, local work-processes, the use of methods, theories and tools in the work-processes, success parameters for a well done job and perception of the commissioning-process' contribution with respect to the improvement of information integration between the various actors. All interviews were transcribed.

3. Tentative findings

In the following the four central communities are described with respect to how knowledge is localized, embedded and invested (Carlile, 2002) and the impact of the standard on the knowledge transfer between the communities.

3.1 The client

The client is an architect and has many years of experience. The client's task is to put the project organization together to solve the task that has been ordered and comply with the City of Copenhagen's policies. In this case, the Children and Youth Administration ordered the school and the Culture and Sport Administration ordered the sports hall. They are responsible for formulating visions and making functional requirements for the project. Historically, both administrations have developed general functional requirements which may form the basis for the preparation of a building program. There had never been a tradition of involvement of the operational users of a building from so early in the building program. In this sense this commission initiative is new. The client's task is to get the services performed in the construction sector's contract system, which includes preparation and conclusion of contracts with architects, engineers, specialist consultants, contractors and client advisers – all those who need to help to carry out a construction project. Furthermore, it is the clients' task to follow up on all agreements that are made, and in this way the client has process responsibility. Process responsibility is about running the process so that the ordering body and all the various construction companies deliver on time, so that the process does not become blocked through the various phases. The key person within the client organization (Copenhagen Construction) the client work together with is a lawyer with respect to the tender documents and contracts and the manager of the department. In addition, the client adviser is the client's main sparring partner. The client perceives the Cx adviser as the Copenhagen Property client adviser. The technical staff in Copenhagen Property has previously had the problem that they have primarily performed emergency operations and have had no time for planning and maintenance. By supporting participation of the technical staff in the construction project with a Cx adviser, the client has experienced that the operational department has become a better project participant, in the sense that the Cx adviser has helped the department to qualify their input for the design process. The regular Cx meetings and the ongoing scrutiny make it possible for the client to take decisions on technical aspects. In previous projects, the client had to spend time searching for the relevant staff in the operating department. The client thinks the Cx log as the Cx advisers' documentation that he has done his work. The client experienced that the commissioning process adds operational experience to the construction project important and challenges the design team on their solutions. Scrutiny processes mean that the client has a denser net to assess the project documentation at each phase, which means that the client can comment on the project documentation, where in the past the client often simply accepted the project documents. The client is very careful to keep the various actors in their roles, and experiences that it can be difficult from time to time to keep the Cx adviser and the team behind him in his role. There can be a tendency for technical staff to come with proposals that are not appropriate since the client thereby risks that the design team can disclaim responsibility by referring to the Cx adviser, who represents the client.

3.2 The operational department

Two years ago, a task force group was set up with four members from Copenhagen Property and Copenhagen Construction, respectively, to develop a concept for participation by Copenhagen Property in construction projects. The group have partly developed an operational log in which they have gathered experience from operations; partly as a process structure for participation in the construction project. The operation of the municipal property is shared between a local operation, with staff from the local users of the property, and a central operation, with Copenhagen Property's own technicians. The structure of the process is that the operation staff should be involved in the conceptual design, project proposal and just before delivery in order to prepare the operating personnel to take over the building. The aim is that the users (end-users, local operations staff and Copenhagen Property's own technical staff) should be able to use the building appropriately and take ownership of it. There have been major problems in deliveries of the new buildings where the users have not been able to figure out how to use and operate the building, which costs a lot of time and money for Copenhagen Property. Therefore, Copenhagen Property has experienced a need to be involved in construction projects as a way to clarify expectations as to: the type of building the users want, how technically complex it must be and the type of skills required by the local operational staff. The task force group follows a number of projects and holds meetings every 14 days. They arrange workshops for colleagues and are continuing their work on the operational log and the process concept. The coordinator's task is to involve the right people from Copenhagen Property at the right time in the construction process in relation to reviewing project documents, including ensuring that they receive information and submit comments for scrutiny on time. The Cx process in this project is an extended process in relation to BtD. In this process, the coordinator has involved technical staff from four different areas: the emergency operation, ventilation, electrical installations and energy management. There is only one engineer with experience within control systems in Copenhagen Property, so he is often busy. He has been involved in the Cx process but has largely left his work to the Cx adviser. In this project, the operational log was split into a Cx log and an operational log. For the coordinator and the technical staff, this meant that they left responsibility for issues in the Cx log to the Cx adviser. Conversely, they used many resources to attend more meetings than usual. The Cx adviser was perceived as the consultant. The coordinator experienced that the Cx adviser was active himself, which she prefers. In other situations, she has experienced Cx advisers expecting that themselves (Copenhagen Property) have to know what different solutions mean and what they should choose. In these situations, the coordinator will retain the Cx adviser in the role as the expert who is to help them. The coordinator assesses that in this project the operational staff have had good opportunities to influence the design process, but this is not necessarily because of the Cx process. The energy consultant company, who are responsible for the technical design convened four workshops concerning plumbing, building automation, lighting and electricity, and fire from the beginning, but this was not part of the Cx process. Already in the making of the construction program, there was much openness on operational requirements and experience. The coordinator perceives the process as a situation in which there is knowledge from each side of a date. In the process, both sides become aware of problems and challenges with design and use of technical systems, for example, she assesses that the Cx meetings strengthen this process and it is constructive that the Cx adviser manages the meetings and gathers the threads. A second version of the operating log has been made based on all projects in which it is used. The adjustment is about reformulating the requirements so they can be better understood by consultants; reformulating simplifications so there are no contradictions; taking out requirements because they are covered by legislation; and adding new conditions. It is a dynamic tool which evolved from being a communication tool into a technical program basis. Entering construction projects involves a responsibility. From sitting outside and criticizing to the active participation and being responsible for the choices made is an issue for the technical staff. At the same time they mentioned that they have had a better understanding of the construction project, the choices taken and the priorities. This also means that the requirements for the operation must be substantiated and not just based on personal opinion. The operational log was therefore sent around to the technical specialists in-house in Copenhagen Property to ensure that the foundation was as it should be. This process has been a learning process and taken time. The function of the log today is to ensure that Copenhagen Property is heard in construction projects.

3.3 The energy consultant

The energy consultant company, which is responsible for the design of the technical system, is a medium sized company. The company is part of the team set up by the main consultant for the design process. The energy consultant distinguishes between integrated energy design, traditional design and follow-up, including the commissioning of the various phases of a construction project. Integrated energy design is about having a dialogue with the architect right from the start of the design process as a way to integrate energy considerations in the design of the building. In this project they used integrated energy design from the start. The energy consultant perceives the strong focus on operation and maintenance early on in the building program as in this construction project as an unusual but important aspect. In this way the operational employee can be seen as a new user. When technicians design the technical systems they use different calculation methods, simulation tools, standards and regulatory basis. The main success criteria for their work are to deliver projects that clients are subsequently satisfied with. It can often be difficult for clients to communicate what it is they want, also because they are often not close to the users. It is best when clients are fully aware of their ambitions for the new buildings. From the consultant's perspective, he believes that the client will have to pay too much for commissioning as it is organized in this project. He is baffled as to why the consultants who designed the systems are not brought in to ensure the operations and the handover to the operational staff, as it is these who know the system best. Now a Cx adviser is paid to follow the entire project. At the same time the Cx adviser has no responsibility for the design. The energy consultant believes that the problem is that the Cx adviser gathers and coordinates a lot of information for the various users to use, but he does so without responsibility. The energy consultant and his team therefore need to check all information, since they are responsible. The consultant points out that the Cx adviser does not do something he should not do in advance. The energy consultant has the perception of the Cx adviser as the client's adviser, including the role that the Cx adviser must gather information from operations and coordinate their contributions. The energy consultant experiences that it is a clear benefit to the process if a Cx adviser arranges to obtain and systematize operating experience and creates forum (Cx meetings) in which a dedicated group of people meet and discuss operation, maintenance and user-oriented features of the building. The commissioning process has meant solutions that users could relate to have been presented early on in the different phases and this has given rise to a number of considerations together with the users early in the project. The process has pushed the focus on user needs and experience to operate the building to earlier in the design process. The consultant's experience with scrutiny is that it has worked well with the various users, but it has given rise to problems with the client-adviser team, i.e. third parties. The user base is the finished building and the issues related to the operation. Third parties, who are also technicians, however, asked about issues that seemed as if they were on a wrong level of detail in relation to the level of the individual phases. The energy consultant assesses that the level of detail for the various design phases is a gray area, and that he experienced problems with both the language and level. The energy consultant perceives the operational log as a collection of everything from small to large. He does not consider the users' requirements in the operational log and in the review as mandatory requirements, but more as a matter of dialogue and clarification from both sides. In contrast to this, the scrutiny comments made by other engineers (third parties) have the style that they think things should be done differently. For the energy consultant, the interaction with the operating team in particular has been good and this counteraction would be beneficial each time in a design process. Scrutiny comments have also had the function that the energy consultants have been able to lean on them and thereby strengthen their own arguments against the architect in the design process. For example it was often pointed out that the technical rooms were too small, and this became the final argument for the architect, who conversely had trouble getting the area consumption to meet the objectives for the building.

3.4 Cx adviser

The Cx adviser comes from a large consulting firm. He has many years of experience in the engineering field. He works with both technical design and commissioning, and he believes it is necessary to design in order to make commissioning lead to constant updates based on the latest standards, techniques and experiences. Furthermore, commissioning means that you know the conditions for a design process, for example the conflict between the architects' prioritization of design and the engineers' need for room for technology and pipes. The Cx adviser perceives that the key success factors of his work are that the building works from the first day and how the building can be serviced has already been thought about. He sees the commissioning process as a task on how to use the various standard templates to achieve a good result, and in this process the Cx adviser is very dependent on the input from the operation. The Cx adviser feels that it is an advantage that there are many users from operating activities, as it gives them the opportunity to understand all the choices that need to be taken in connection with a construction project. Copenhagen Property and Children and Youth Administration are also challenged in terms of the interface they have built around their two-part operation. The two-part operation has meant that certain concepts for solutions have been established that are not necessarily optimum from the standpoint of energy. Therefore, it is beneficial to have both parties in the commissioning process. He believes it is necessary to separate the operational log and the Cx log as many things in operational log are outside the scope of the technical systems that are the commissioning task.

4. Discussion

After several years of increased demands on buildings' energy performance in Denmark, the experience is that there appears to be a large gap between the designed and expected energy consumption in the design phase and the actual energy consumption during operation. This has centred focus on the need for information integration across construction projects and large operating departments. In Denmark, commissioning is one of the upcoming methods for handling this problem. Commissioning is a quality assurance system that is designed as a project delivery. However this analysis shows that the transition towards design and operation of buildings with high energy performance is not only about the creation of information integration across the design phase and use phase based on existing knowledge, which can be ensured through a quality assurance system on each project. Rather, there is a need of development and adaptation of practices of the involved communities based on a mutual learning process. This raises the need of evaluating critically which potential boundary objects that may function as information integration structures in construction projects and support communication and coordination across design and operation of buildings.

The experiences from the case shows that the different commissioning objects are not stabilized as boundaries objects that coordinate work processes across the various actors. The tendencies are that the different objects structures information integration in different ways and new dilemmas emerge in the interaction between the various actors. The findings illustrate that (i) all communities benefit from the Cx meetings, where information is transferred, translated and transformed across the different communities. The meeting structure has contributed to the operational department have had a better understanding of the construction project, the choices taken and the priorities, which in turn may have contributed to a generalisation of the operational log. At the same time the increased possibility of knowledge creating across the boundaries, may shape new priorities in the design work in favour of operational conditions. (ii) The Cx-log is not established from the beginning with articulated client requirements for the technical system, but is built up through the design process as a common checklist. This point to the fact that client requirements for the technical system it is not common knowledge that already exist. From the perspective of the energy consultant, priority of operational conditions and visibility of the "new user" can qualify the client's requirements for the building. This makes it easier to deliver a building that lives up to expectations. However the technical system is separated from other operational condition, which may increase the risk of a low priority of other operational condition. The new version of the operational log as earlier mentioned may have the potentials to be a new boundary object in future projects to increase collaboration across actors on the building's energy performance. (iii) The Cx scrutiny is a standardized scheme in which all the different communities have the opportunity to comment on the project documentation in the different phases. The results show that where the users and the operations department commented on the different solutions and had clarifying questions, the client adviser's technical staff suggested new technical solutions. In this way, the two columns of the scrutiny table act as two competing engineering paradigms rather than qualification of the design team's proposal. From the client's perspective, increased process documentation may increase the client's possibility for controlling the project material. However use of scrutiny may also take time from the design process as it takes time to fill in answers in the table. In addition competing engineering paradigms may keep both design methods and solutions in traditional design mode. In worst case it may take focus from adaptation and development of new design methods and solutions based on experiences from operation of buildings.

The experience from this case suggests that instead of maintaining the technical solutions in the form of standard methods and new consulting services, which follows as a natural extension of a project focus, it may be more appropriate to consider the various ways this process can be organized. Aspects of commissioning can contribute to this, but this solution should be challenged on the relevance of each element and where the function should be placed.

1. When placed with a third party, this function can increase the control aspect of the client, but will conversely be a costly solution. At the same time, it can give rise to competing engineering paradigms, which can detract focus from the new user and inhibit development of new design methods based on new perspectives.
2. When placed with the consulting engineers, this function can support the development of new design methods and be a natural development of their design delivery. Costs can be reduced, since there will not be two engineering consulting companies that have to know the technical system in detail, but conversely control aspects will be reduced.
3. When placed with the operational department, this function can strengthen their capacity on this area and support their organisational development, but it may require specialist knowledge that can be difficult to maintain in operation organisations

5. Conclusions

In the context of new priorities in construction, there will always be a need for new forms of information integration between new actors. It may seem that "technical solutions" are made before "ongoing learning processes" in which new themes are articulated and understood across the different knowledge boundaries. Since there is a tendency for "technical solutions" to remain after a project, it seems that a solution strategy with development of standards and new consulting services could lead to increased fragmentation of construction projects. In addition the case illustrate that the commission process influence not only knowledge sharing across different communities but also the distribution of roles, responsibilities and control. Based on these results it will be useful to know more about, the socio-technical aspects of the development of new forms of information integration in construction projects in the context of new priorities in construction.

Text Analytics on Construction Tender Documents for Project-Oriented Risk Mining

Jee-Hee Lee, JeongWook Son and June-Seong Yi

Ewha Womans University, Korea
Email: jeeheelee1984@gmail.com

Abstract

Construction tender documents contain owner's project requirements so that a contractor can make project plan. However, tender documents might not always be clear and adequate. Furthermore, since there are many potential project risks behind the documents, close analysis on tender documents should be implemented. This paper discusses a project-oriented risk mining approach which could detect and extract project specific risk factors based on text analytics. From the risk mining process composed of text mining step, risk classification step and risk assessment step, project specific risk factors could be effectively managed initially. Furthermore, the project-oriented risk mining approach is expected to effectively reflect project characteristics to the project risk management and could provide contractors valuable business intelligence.

Keywords: Tender document, Risk management, Project-oriented management, Text mining

1. Introduction

Contractors can understand owner's design intent and requirements from the tender documents. However, the tender documents might not always be clear and adequate. Brook (2004) indicated that major problems associated with quality of information in drawings, specifications and bills of quantities include missing information, late information, wrong information, insufficient detail, impracticable designs, inappropriate information, unclear information, provisional information, poorly arranged information, uncoordinated information and conflicting information (Laryea 2011).

Besides, as construction projects are getting bigger and more complex, especially in international projects, close analysis on tender documents is very required. Although the tender documents are crucial for understanding project characteristics, tender document analysis is not sufficiently conducted in many projects. According to one of the major contractor's internal survey, most of cost overrun factors in international projects are related to construction tender documents, such as poor review on ITB (Instruction To Bidders), design errors and omissions, and discrepancies among tender documents. This shows tender document study should be managed from a risk management aspect since many potential project risks are existed behind the documents.

There are many concerns regarding risk management skill as many contractors suffer major losses in international projects. In the view of risk management's life cycle, the effect of risk management in the early stage is greater than the late risk management while available information is poor at a beginning step. Because tender documents are the only information available at the project initial phase, document-based risk analysis should be conducted. Moreover, unclear and wrong information in the tender documents should be clarified in order for maximizing initial risk management effects.

Even though the importance of early risk assessment and management have been emphasized, however, current risk management practice at the project beginning step does not fully deal with project risks. Majority of typical risk management studies focus project's external and unexpected risks on such as political risks and financial risks. Those external risks are hard to manage and prevent, risk management should be concentrated on project inherent risks.

In the real construction world, there are many situations where the quantitative and detailed information to evaluate uncertainty is not available. These conceptual factors can be expressed in qualitative or linguistic terms, that is, so called fuzzy information (Kangari, R. and Riggs, L. S. 1989). This explains those linguistic risk terms should be managed in order to assess project's potential risk factors. Therefore, this study suggests a project-oriented (internal) risk-mining framework which can detect and extract project-specific linguistic risk factors based on text analytics for tender documents.

2. Background

2.1 Overview of current research

Extensive research has been done in risk evaluation and risk management at the project beginning step. Zhi, H. (1995) developed a method of managing various risks for overseas construction projects and how to effectively identify the vital risks in overseas projects. Gunhan and Arditi (2005) evaluated risk factors affecting international construction projects by surveying the executives in charge of international construction of large U.S based contractors. Sonmez et al. (2007) presented a quantitative methodology to determine financial impacts of the risk factors during the bidding stages of international construction projects. Lin and Chen (2004) suggested bid/no-bid decision making by using a fuzzy linguistic approach. In that approach assessments were described subjectively in linguistic terms, while screening criteria were weighted by their corresponding importance using fuzzy values.

However, almost the whole risk evaluation and risk management studies are weighted toward high level of risks, such as political risks and financial risks, not project-oriented (low-level) risks. Moreover, most existing risk assessment systems are based on quantitative techniques which require numerical data. However, much of the information related to risk analysis is not numerical. Rather, this information is expressed as words or sentences in a natural language (Kangari and Riggs 1989). Besides, many researches relies on survey-based statistical analysis which could be easy to have biased personal opinion and experience. That are the reasons current risk evaluation and risk management studies does not fully deal with each project's characteristic. Therefore, this study approaches from the bottom of the project risks, which is document-based analysis and project-oriented (internal) risk analysis.

2.2 Research Objective and Research Question

Risk management is typically carried out during a whole project life cycle. If risk evaluation is not sufficiently performed and project risks are not fully detected at the project beginning step, however, potential project risks could be presented during the project. In other words, successful project performance cannot be guaranteed without pre-emptive risk management in the project early stage.

Based on this premise, this study suggests a framework which gives a concept of project-oriented (internal) risk mining in order for preventing and minimizing of great losses caused by poor risk evaluation at the project initial phase (tendering process). To extract project-oriented risks, this study concentrates on project tender documents which includes many project potential risks. However, close analysis on huge amounts of tender documents is always a challenging task since the tendering period is not enough. Furthermore, tender documents might not always be clear, consistent and adequate. Thus, text mining concept is adopted in this study in order to analyse large amounts of tender documents and extract related risk factors. The project-oriented risk mining process is expected to be used as bid decision making materials so that contractors can judge whether the project is profitable or not in advance.

From the previous literature review, not only project external risk (high-level risk) factors but also project-oriented risk (low-level risk) factors should be managed in the early stage of construction project. Because project tender documents contains many information about project characteristics, this study should start with analysis on tender documents. The concept of this study has been named as "Project-oriented Risk Mining". In order to proceed the study the following questions should be addressed in advance:

- What type of risks should/could be solved?
- What kinds of project-oriented (internal) risks are existed in tender documents?
- How to identify project-oriented (internal) risks?
- How to extract/mine text-based risk factors?

What are the proper evaluation method for various types of risks?

3. Research Framework

3.1 Project-Oriented Risk

Project-oriented risk could be defined as project-specific risk factors which exist project inside. Project-oriented risk is related to the quality of tender documents' information in drawings, specifications and bills of quantities included missing information, wrong information, insufficient detail and impracticable design, etc. Poor quality tender documents can lead to inaccurate estimates, higher margin in bids, claims and disputes (Laryea 2011).

From a review on previously performed project documents, we could derive some risk types associated with tender documents as follows:

- Problems caused by specific clauses or terms written in tender document
- Problems caused by omitted information in tender document
- Problems caused by discrepancies between information
- Problems caused by wrong information in tender document

Those types of risks related to the tender documents could be identified as project-oriented risks, and those risk factors should be detected at the tendering process for successful project.

3.2 Text Analytics for Tender Document

Tendering is one of the stages in a construction project that requires extensive information and documents exchange. Such tender documents often contain the information about a client's project plans so that a contractor can price it (Laryea 2011).

Tender documents may include (Designing Buildings Wiki 2015):

- A letter of invitation to tender
- The form of tender
- Preliminaries : including pre-construction information and site waste management plan
- The form of contract, contract conditions and amendments. This might include a model enabling amendment for building information modelling (BIM), making a BIM protocol a contractual document
- A tender pricing document (or contract sum analysis on design and build projects)
- Employer's information requirements for BIM
- Design drawings, and perhaps an existing building information model
- Specifications

Since tender documents are contractual documents, the information written in tender documents have legal force. If a contractor misses some wrong information or omitted information in tender documents during tendering process and decides to proceed the project, the contractor should take the risks which could be arise due to the wrong or omitted information. To prevent and take pre-emptive action on the project risks hidden in tender documents, tender documents analysis should be managed from a risk management aspect.

Because construction tender documents are written in text which is unstructured data, various type of data analytics, such as text analytics, are required. Text analytics helps analysts extract meanings, patterns, and structure hidden in unstructured textual data. The term "text analytics" has evolved to encompass a loosely integrated framework by borrowing techniques from data mining, machine learning, natural language processing (NLP), information retrieval (IR), and knowledge management (Chakraborty G. et al. 2013). Text analytics is useful method to analyse great amounts of documents with short tendering period. Text analytics enables to have term frequency and related terms in documents so that potential risk factors existed in tender documents could be detected.

3.3 Text Analytics for Tender Document

This study defined the concept of risk mining as a progressive methodology which detect unstructured textual data, and categorize risk types, and assess them. Figure 1 shows the project-oriented risk mining framework. This framework is divided into two parts, which is risk identification step and risk mining step.

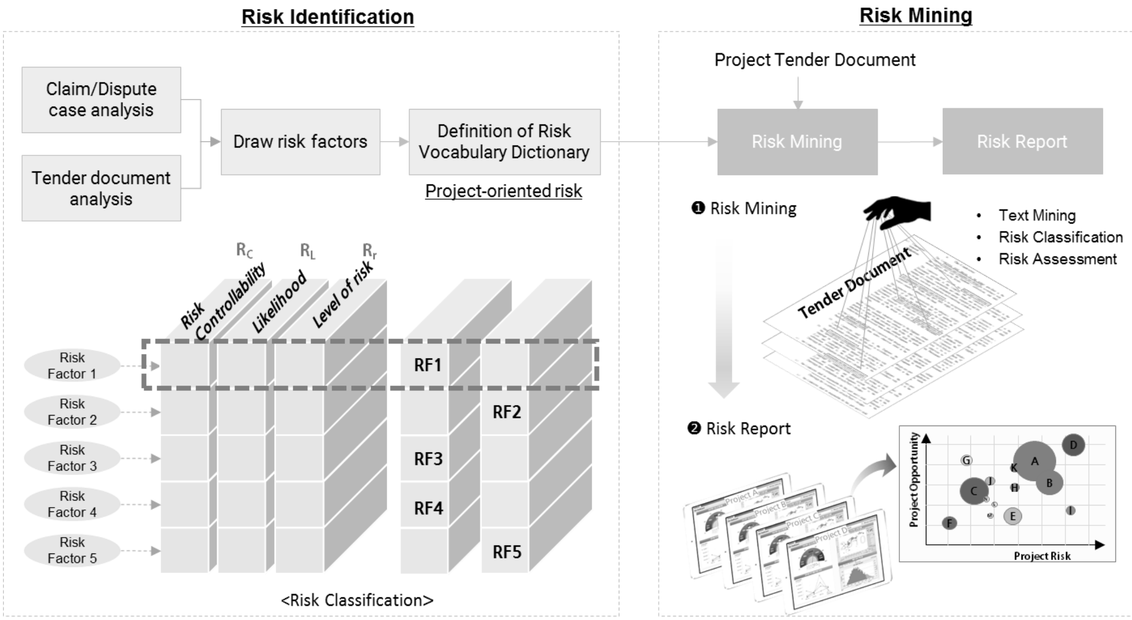

Figure 1 Project-oriented risk mining framework

'Risk Identification' step is based on two types of literature review, previously performed project's tender document analysis and construction claim/dispute case analysis. From the previous project cases which experienced losses because of a poor analysis on tender documents, we could understand what issues written on tender documents influenced the project's success and fail. Those issues might be the type of project-oriented risk factors. Another way to draw project-oriented risks is investigation into construction claims and disputes related to the tender document problems. Since claims and disputes are caused by project various risks, we could figure out project-oriented risk factors from claims and disputes cases. Those risk factors derived from the literature reviews could be collected in order to define risk vocabulary dictionary. The risk vocabulary dictionary could be used at the 'Risk Mining' step during imported project tender document's risk assessment.

In the 'Risk Mining' step, newly imported tender documents are firstly text-mined according to the risk vocabulary dictionary, and each risk terms are categorized by risk categorization step, and finally evaluated at the risk assessment step. The result of risk mining is summarized as a risk report. The risk report shows project risks and project opportunities so that risk mining results could support project bid decision making.

4. Illustrative Example

To illustrate the proposed research framework, this study performed risk identification step as an illustrative example using construction cases on adjudication. In this example, we investigated into construction adjudication cases in order to identify risk factors. Project-oriented risk factors could be figured out from the claims and disputes cases. For the purpose, 549 adjudication cases were collected from 1999~2015 in UK construction industry. Text mining for analysis of construction adjudication cases was conducted using SAS Text Miner 13.1.

Since this illustrative example was performed for extracting project-oriented risk factors from the claims and disputes cases, the adjudication cases which written in text was analysed according to the following steps. Text import, text parsing, text filtering, and text clustering. Text importing is the first step in the text mining process. Collecting and setting up textual data is performed in the text importing step, and the source data is imported into the text mining tool. The textual source data is called as 'corpus'. Corpus is a large set of texts, and they are used to do statistical analysis and hypothesis testing (Wikipedia 2015). After the text data is imported, it is ready to be analysed.

Once the text-based documents are imported, the documents should be disconnected in order to quantify information about the terms. This step is 'text parsing' step which convert the collected textual documents (unstructured form) to a structured form using vector representation.

Table 1 Results of text parsing (partial)

Terms	***Role***	***Term Frequency***	***Document Frequency***
adjudicator	*Noun*	*13,772*	*343*
decision	*Noun*	*10,520*	*366*
clause	*Noun*	*5,331*	*261*
payment	*Noun*	*5,394*	*327*
notice	*Noun*	*4,668*	*315*
issue	*Noun*	*4,465*	*355*
pay	*Verb*	*4,026*	*347*
provide	*Verb*	*3,794*	*352*
cost	*Noun*	*3,645*	*321*
agree	*Verb*	*3,477*	*363*

There are two broad-based approaches to analysing text. The first is the bag-of-words method, where the basic assumption is counting words in the text, plus understanding how these words are syntactically (structurally) related to each other in regard to laws of grammar, etc. This method is sufficient to summarize and classify text documents. The second approach, which is linguistic, posits that truly understand and classify text, you have to move beyond syntax (structure) to semantics (meaning of words). In order to apply either approach, the text document is first parsed to find the words contained in it (Chakraborty G. et al. 2013).

The first step of text parsing begins with breaking down the text stream into terms. Texts in the documents are tokenized and normalized during text parsing step. Table 1 shows the result of text parsing of construction cases on adjudication. Typically, ignoring parts of speech, ignoring types of entities and attributes are additionally conducted in order to make text parsing more simple and fast.

Next step is 'text filtering'. Text filtering eliminates extraneous information caused by the presence of noise terms and other terms, so that only the most valuable and relevant information is considered. Moreover, user-defined terms could be excluded at the text filtering process. Some general construction terms, such as 'contractor' and 'construction', etc., was added to the stop list to focus on the terms and documents that are most likely to enhance the result. Creating appropriate stop list is crucial in obtaining valid and useful results. Figure 2 shows the text filtering process using stop list.

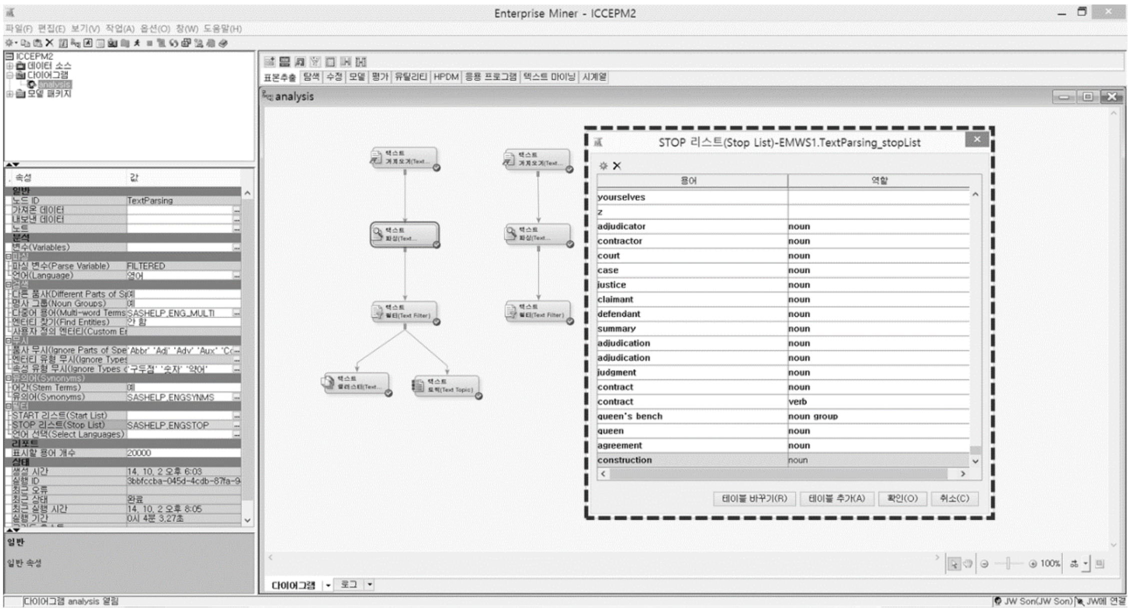

Figure 2 Text filtering process using stop list

After text parsing and filtering is finished, 'text clustering' could be performed in order for grouping a set of related risk terms. Text clustering is the task or grouping a set of text words that wards in the same cluster are more similar to each other than to those in other clusters. Text clustering enables to define, discover, and modify sets of topics contained in the documents. In order for text clustering two algorithms are available. The expectation maximization algorithm clusters documents with a flat representation, and the hierarchical clustering algorithm groups clusters into a tree hierarchy. Both approaches rely on the singular value decomposition (SVD) to transform the original weighted, term-document frequency matrix into a dense but low dimensional representation (SAS 2014).

Table 2 is the text clustering result of construction adjudication cases. Each word included individual cluster represents each clustered documents. However, the clustered words do not give detail information about cluster's distinction. Even if the word groups were made by some clustering algorithm, it is difficult to define individual cluster's distinction without understanding the context where the term is being used. Therefore, examining full text and related sentence where terms are being used should be performed repeatedly to define each cluster's topic. As a result, 6 clusters were identified as follows:

Table 2 Result of text clustering

Cluster 1	***Cluster 2***	***Cluster 3***	***Cluster 4***	***Cluster 5***	***Cluster 6***
damage	*breach*	*completion*	*structure*	*change*	*cost*
delay	*design*	*plan*	*installation*	*document*	*fee*
date	*document*	*debate*	*industry*	*clear*	*solicitor*
notice	*contract*	*certificate*	*supply*	*engineer*	*pay*
extension	*evidence*	*damage*	*light*	*variation*	*evidence*
provision	*place*	*complete*	*site*	*breach*	*money*
payment	*detail*	*submission*	*house*	*comply*	*letter*
claim	*price*	*cross-claim*	*fee*	*dispute*	*instruct*
challenge	*site*	*doubt*	*contend*	*state*	*submission*

- Cluster 1 : Liquidated damage related terms
- Cluster 2 : Design liability related terms
- Cluster 3 : Practical completion related terms
- Cluster 4 : Site establishment liability related terms
- Cluster 5 : Variation related terms
- Cluster 6 : Payment related terms

The result of text clustering could be used to define risk vocabulary dictionary. The risk related terms by risk type is potential risk factors, and those terms enrich the risk vocabulary dictionary. By drawing risk factors from many cases, risk vocabulary dictionary could be used at the risk mining step during imported project tender document's risk assessment.

5. Discussions

This study discusses a project-oriented risk mining approach which could detect and extract project specific risk factors based on text analytics. Moreover, a part of risk identification step which is included in research framework was conducted as an illustrative example using construction cases on adjudications. However, the result from the adjudication cases should be linked to the result from tender document analysis which did not deal with at this illustrative example. Since all the terms derived from the adjudication cases might not directly matched to the tender documents, further study should be required to make project-oriented risk mining framework more effectively. If the study of previously performed project's tender documents will be followed later, more practical risk factors could be derived. Using those risk factors, project-oriented risk mining process could be more materialized with computer-aided skills in the future study.

6. Conclusions

The purpose of the study is to propose a new approach for managing text-based project-oriented risks. Since available information in the early stages is not enough and clear, identifying owner's design intent written in tender documents is important for proceeding construction projects. However, current risk evaluation and risk management studies dose not fully deal with project risks. Thus, this study presented project-oriented risk mining approaches from the bottom of the project risks, which is document-based analysis, using text analytics techniques. Although the illustrative example was only a part of drawing project-oriented risk factors, this study is one of the meaningful attempts to investigate unstructured text data in construction field. Furthermore, the project-oriented risk mining approach is expected to effectively reflect project characteristics to the project risk management and could provide contractors valuable business intelligence.

Complexity and Energy Performance Contracting: the Case of Street Lighting

Frédéric Bougrain

CSTB – Université Paris-Est, France
frederic.bougrain@cstb.fr

Abstract

There has been a renewal of public-private partnership (PPP) in France after 2004. Until 2013, this procedure was relatively popular to deliver integrated solutions to public authorities who were demanding for packaged product and service delivery. Street lighting projects aiming at reducing electricity consumption are dominant among PPP. These projects are a category of energy performance contracting (EPC). The question is why EPC is dominant for street lighting projects and not for buildings. A case study focusing on a street lighting project indicates that they are less complex. Uncertainty is limited and beneficiaries have no influence on the end result whereas occupants can have a strong impact on the energy consumption of a building. Moreover, formal contracts are adapted to this type of projects with limited uncertainties and relational governance can be limited.

Keywords: PPP, complexity, governance, public lighting, energy performance contracting

1. Introduction: private finance procurement in France

France has a long experience in private finance procurement. It concerns mainly infrastructure projects where an asset (such as a road) is provided for which users pay directly. The first concession arrangement was signed in 1554 for the construction and maintenance of a canal over a period of ten years (Bezançon, 2005). During the 19th century, the concession system was dominant for all public works. Contractors were systematically associated to maintenance works for six to ten years. More recently, during the sixties, concessions mainly concerned public infrastructures such as bridges, tunnels, urban facilities and roads (motorways). Under this scheme, the concessionaire is partly paid by the users of the public service conceded.

During the late eighties, some schools and prisons were delivered under a Design, Build, Operate and Finance scheme. However, the procurement method was opaque and it led to illicit agreement practices between contractors. Thus, public private partnership (PPP) for buildings was banned for about ten years and the development of the market in France was delayed. However, most large French contractors were able to benefit from the PFI experience in the UK.

At the beginning of the 21st century, there was a strong debate for the renewal of PPP in France. Architects were strongly opposed to any kind of PPP for buildings. They considered that contractors would become relatively more powerful and that financial issues will took over architectural matters. Conversely, large contractors saw PPP as an opportunity to modify their traditional business models and to move into new kinds of value-added activities. Between 2002 and 2004, several ministries (home Affairs, Justice, Health and Defence) introduced a new legal framework for projects concerning facilities such as prisons, police stations, and healthcare facilities. Finally, in June 2004 a new law was enacted to spur partnership contracts ("Contrats de partenariat"). It was strongly influenced by the Private Finance Initiative in the UK. From June 2004 to December 2013, 194 contracts were signed representing an investment of approximately 14 billion euros (table 1).

Table 1: Economic value of Partnership contracts at the end of 2013[1]

Actors	*Projects signed*	*Investment (million €)*	*Global value (million €)*
Local authorities	*145*	*4 119*	*10 185*
State	*49*	*10 346*	*26 436*
Total	*194*	*14 465*	*36 621*

Source : CEF-OPPP (2014)

Knowing that public investment reaches about 90 billion euros every year, the vast majority of investments in the French public service is still procured through conventional means. Partnership contracts were mostly used for buildings at the State level, and for urban facilities, at the local level (table 2).

Table 2: Sectoral breakdown of partnership contracts signed at the end of December 2015

Actor / Type	*Local authorities*	*State*	*Total*
Building	*34*	*32*	*65*
Sports and cultural infrastructure	*22*	*2*	*25*
Energy / waste	*11*	*11*	*22*
Urban facilities	*63*	*0*	*63*
Information and communication technologies	*13*	*4*	*17*
Transport	*10*	*6*	*16*
Training	*0*	*1*	*1*
Total	*153*	*56*	*209*

Source : MAPPP (2015) - http://www.economie.gouv.fr/ppp/contrats-signes

[1] After 2013, the number of deals collapsed. 9 and 6 projects were respectively signed in 2014 and 2015.

Among urban facilities, street-lighting is dominant. These contracts aim at refurbishing street lighting in order to reduce the electricity consumption of local authorities. As such, they can be associated to energy performance contracting (EPC). According to the European Parliament's definition (2012), "*energy performance contracting means a contractual arrangement between the beneficiary and the provider of an energy efficiency improvement measure, verified and monitored during the whole term of the contract, where investments (work, supply or service) in that measure are paid for in relation to a contractually agreed level of energy efficiency improvement or other agreed energy performance criterion, such as financial savings*".

Partnership contracts have seldom integrated issues dealing with energy performance in buildings. Conversely, cutting energy consumption was the main target of PPP focusing on street-lighting. The aim of this paper is to understand this gap.

To launch a partnership contract, it is necessary to prove that the project is "urgent" or "complex" or brings value for money. More than 90% of PPP projects were considered as complex.[2] Thus, the paper will examine the notion of complexity in construction and its impact on project governance. Then, a case study focusing on street lighting will be presented. The aim of the discussion will be to understand why energy performance contracting is dominant in street lighting projects and frequently omitted in building projects.

2. The impact of complexity on governance

2.1 Complexity in construction project

It is widely recognised that construction projects become progressively more complex (Baccarini, 1996). This complexity is also put forward by Hobday (1998) who introduced the notion of complex products and systems (CoPS) to characterise one-off projects. While the focus is on the production process with goods and services, the emphasis with CoPS is on design, project management, systems engineering and systems integration. Several dimensions characterise complexity: the degree of technological novelty, extent of embedded software in product, quantity of sub-systems and components, feedback loop from later to earlier stages, uncertainty/change in user requirements… As construction is moving away from its production-based focus and is developing new service activities (financing projects, operating and maintaining systems…), interfaces are multiplied, and project complexity becomes stronger. Project management does not anymore concentrate on the internal project team and external supply chains. It also integrates downstream service delivery. (Alderman et al., 2005).

This move from the building activity to the service provided by the built environment (Carassus, 2002) is accompanied by a change of procurement. Traditional design and build contracts based on input specifications are more and more replaced by service-led contracts where the output to

[2] A new law will be enacted soon. The aim is to simplify all sector-specific legislation and to comply with the European directive on public markets. According to the first draft (July 2015), partnership contracts will only be signed if they offer value for money.

be delivered is specified. The competitive dialog procedure is particularly adapted to these situations since it helps to match the demand of the client with the possible solutions that contractors can offer (Hoezen et al., 2010). According to Lewis and Roerich (2009), it is possible to assess the complexity of the procurement process in terms of two dimensions: performance complexity and infrastructural complexity. The first refers to "*a function of characteristics such as the level of knowledge embedded in the performance*" (p.127). The second refers to "*the complexity of the infrastructure through which performance is enacted*" (p.128). According to this framework, traditional design and build contracts based on input specifications would be considered as less complex in terms of performance than service-led contracts which go further than design and build and encompass operation and maintenance.

Complexity can change over time. Wang and von Tunzelmann (2000) show that each functional area of the firm (technology, markets and products, production processes, administration and management) is in interaction with each other and that the evolution of the complexity of one function will impact other functions. Complexity will also depend on the competencies developed by public authorities. This issue is central for the European Commission (2004) who considers that a public contract is particularly complex when the contracting authorities*: "(1) are not objectively able to define the technical means (...) capable of satisfying their needs or objectives, and/or (2) are not objectively able to specify the legal and/or financial make-up of a project*."

2.2 Complexity in EPC

Simple building constructs cannot be associated to CoPS. Conversely, EPC for buildings are complex on several dimensions:

1. Design based on collection of information and data, and dynamic thermal modeling and simulation: Dynamic thermal modeling and simulation is a complex activity as illustrated by the frequent gap between predicted energy performance of buildings and measured energy use once buildings are operational (de Wilde, 2014).
2. Works such as the removal and installation of efficient heaters, measurement and monitoring equipment, insulation of buildings, cover a broad range of activities and usually involve subcontractors. Moreover, works usually concern buildings with different architectural style, different year of completion…and require the development of specific technical solutions. Works are also done in occupied buildings and they have to take into account the occupants to avoid disturbances and conflicts.
3. Operation and maintenance of buildings: the performance of these activities is based on day-to-day maintenance but also on occupancy conditions. To reduce the impact of users during the operation of the building, the operator may develop actions to promote environmental awareness. The complexity is due to the necessary cooperation between two actors (the operator and the occupants) with antagonist goals.
4. Project financing: The financial arrangement is very complex. There are mainly two financing approaches: self-financing or third-party financing (Lee and al., 2015). In some cases, project financing is made with a mix between debt and equity. Public authorities

who are not familiar with these complex financial schemes regularly receive the support of lawyers and financial consultants.

5. Measurement and verification: they are the cornerstone of EPC since it is used to allocate risks between the ESCO and the client, to assess energy savings and reckon penalties / bonuses, to monitor equipment performance and to improve operations and maintenance (USDE, 2015). There has been effort to standardized M&V by developing protocols. Moreover, technological development in monitoring and data mining techniques have contributed to improve performance predictions and building energy management decision-making (Ahmed et al, 2011). However, this is still complex since it is difficult to get reliable building operation data before the signature of the contract and to monitor behavioural changes during the project life time.

Moreover, project complexity is influenced by the experience of the stakeholders with EPC projects. Energy Service Companies (ESCOs) which are at the core of EPC are not equally developed among countries. Bertoldi and al. (2006) classified French ESCOs in the “second European league”. Similarly, public authorities who have a great experience with delegating the management of public services are still not familiar with performance contract and performance procurement process. As indicated by Hartmann et al. (2010), public authorities need to develop capabilities to contract for service-led projects and manage the relationships with their service providers. Developing simultaneously contractual and relational capabilities is difficult since contractual documents are still the main references.

2.3 Governance issues

Developing a transaction cost analysis, Winch (2001) considers that low asset specificity, low transaction frequency, and high uncertainty characterise construction. According to this theoretical framework, hierarchy should be preferred to drive construction procurement because of the uncertainty surrounding the project (unknown natural conditions, temporary coalition between actors, unique features of each project). However, market governance is the most adapted to clients’ preferences since asset specificity is low (resources required are available from a large number of suppliers and contractors) and transactions are not frequent (even experienced clients do not procure many buildings every year). The move toward service-led projects modifies this framework and requires more contractual safeguards to mitigate the uncertainty (Hartmann et al., 2010). According to Bijlsma-Frankema and Costa (2005), the effectiveness of control of formal contracts depends on three elements: (1) the codification of the tasks and the behaviours, and the measurability of outcomes; (2) the monitoring of the actions performed by the parties; (3) the creation of a structure that enforce the contract.

However, formal contracts are difficult to specify for service-led projects since outcomes are frequently intangible. Moreover, service-led projects have a longer lifespan and are subject to technological changes. Specifying everything ex-ante would raise transaction costs and render the contract difficult to enforce. Indeed, it would be necessary to create a specific structure in charge of monitoring opportunistic behaviour and applying contractual clauses. This would be costly and would create additional complexity. Consequently, it is more efficient to accept incomplete contracts, to introduce some contractual flexibility and to rely on relational governance and trust between partners to avoid conflicts. "*Relational governance refers to those inter-organizational exchange mechanisms that are not sanctioned through formal contractual positions (…) but are manifest in custom and practice*" (Roehrich and Lewis, 2010, 1157). Relational governance has its own enforcement mechanisms such as threat of social sanctioning and reputation effects. Formal contracts and trust are complementary. The negotiation process that leads to the contractual agreement is frequently at the origin of a common understanding between parties. The contract also offers protections necessary for the creation of a relationship based on trust. It is a solution to enforce the trust between partners and to limit opportunism.

3. Case description: the EPC dealing with street-lighting in two municipalities[3]

3.1 The project and its context

The PPP project concern two municipalities: city A and city B hosting respectively 117 000 and 23 000 inhabitants. Most street lighting facilities of city A were outdated (more than 45 years old) and highly inefficient. In 2007, 26% of the 5298 lights would have required to be replaced within five years and 40% within two years. The power of the lighting system was also defective. Consequently, the network was not anymore safe and reliable. Operation and maintenance were entrusted to municipal employees and outsourced to one company who signed a one year contract renewable three times. The situation of the neighbouring city (B) was less dramatic. Only 25% of its 2 647 lights had to be replaced in the short run. One private partner was in charge of operating the network. Indeed, in 1994, this city signed a PPP including financing, operation, maintenance and renewal of street lighting and traffic lights.

Annual operating costs were different between cities. City A spent about EUR 335,000 each year. City B with a network twice as small spent EUR 400,000. In 2004, competencies dealing with street light were transferred to a regional community. PPP was seen as the solution to modernise the lighting network and to introduce environmental criterion and energy performance objectives. City A had a limited borrowing capacity and was not able to borrow €30 million for the modernisation of its public lighting network.[4] City B already experienced PPP and was also looking for a solution to finance, renovate and operate its network.

[3] Since there is apparently nothing in the literature about street lighting the case study approach appears appropriate. It is based on face-to-face interviews with the client, the legal consultant, and two people representing the private partner. A report comparing the conventional public procurement process and the PPP option was also used as complementary source of information.

[4] At that time, PPP was still seen as a way to account public investments as off the balance sheet. According to the Eurostat rule in 2004, it was possible to classify investments made through PPPs as non-governmental if the construction risk and either availability or demand risk were transferred to the private operator. Thus, debt hiding was a motivation for PPP. Since 2011, both existing and new projects have to be considered as public debt. "*On the balance-sheet, the capital value of the investment is recorded within the assets, while the already-paid investment and the remaining debt are recorded within the liabilities*" (Buso and al, 2013).

The criterion of complexity has been put forward to justify the PPP procedure. Both municipalities did not have the technical know-how to refurbish street lighting. Moreover, the regional community who represented both municipalities and took in charge the project had no expertise to assess the level of investment and to operate and optimize the energy related installations.

Legal, financial and technical consultants assisted public authorities during the redaction of the comparative analysis and the competitive dialog. According to the public sector comparator, PPP offered the best value for money both in terms of costs and service quality. The call was launched in December 2006. The first round for the competitive dialog was organised in September 2007 and the second in November. The contract was awarded in June 2008 and signed in July for 20 years. The company, who won the competition for the deal, covers the entire value stream of public lighting, from design, to renovation works and operation. Consequently, there was no need to create a Special Purpose Vehicle as for most PPP projects. The company borrowed money to one bank. The initial costs of the deal reached EUR 92.3 million. However, it was renegotiated during refurbishment works due to a decrease of interest rates. Thus, the final deal reached EUR 86 million over the 20 year period.

3.2 The complexity of the project

According to Wang and von Tunzelmann (2000), complexity covers several dimensions: the technology, the markets and products, the production processes, and the administration and management. The complexity of this project mainly concerned the technological and organisational dimensions:

- A large part of civil engineering was performed with micro slicers[5] in order to reduce both the time in which roads cannot be used and the quantity of excavated volume. The private partner also anticipated future works by performing all civil engineering during the first three years of the contract. In the future, when a cable will be laid, no additional trench will be opened. This approach minimised the environmental impact and the nuisance caused by the construction sites.
- The use of the micro slicers completely changed the organization and the conduct of the project. The work was closely coordinated with private companies in charge of managing the gas network and relevant community services. The objective was to avoid interventions from municipal employees shortly before or after the action of the private partner. A specific team was also created to inform residents about the works in progress. Moreover, to optimise the micro slicers, trenches had to cover a length of 500 meters for one week. Such length was unusual and required further communication.
- The installation of a centralised control station was another major innovation. It is commonly used for building but it was the first time for public lighting. Moreover, a wireless network was set up to link luminaires to the central station. This solution aimed

[5] With the traditional approach, the company digs a trench of 80 cm deep and 40 cm width while with this technique, the hole is limited to 35 cm deep and 15 cm width. This technology is traditionally used for the installation of fiber optics in the countryside.

at monitoring the intensity of every light[6] and providing complementary services to local authorities (such as video protection, tricolour stop lights).

3.3 Results

The private companies renovated 70% of the street lighting system on time (at the end of the contract, 95% of the park will be renovated).[7] By concentrating most of the renovation works on the first three years, the goal of the company was to reduce as soon as possible the power of the network by 38% and to reach its energy performance objectives on the long run. Over the 20 year period, total energy consumption has to reach 94 GWh. If the savings are not achieved, the private partner will pay compensation. Conversely, gains will be invested in energy performance works. However, there are no yearly milestones. The private partner just needs to write a report every year in order to present how contractual obligations are respected. Public authorities also hired a subcontractor who ensures that the private company adheres to the performance and standards stipulated in the contract.

After two years, the energy consumption was slightly over its target. However, the private partner was still optimistic since the centralised control station was not operational in both cities during the first years of the contract. Moreover, life cycle costing approaches were not neglected because the operator contributed to the elaboration and he success of the deal. According to Swaffield and Mc Donald (2008) and Rintala (2005), this issue is frequently ignored in PPP projects because budgets are constrained, clients are unable to understand the maintenance requirements and the associated costs, and there is a lack of information about the different options and about the past performance of products. Moreover, operators have usually less influence on the service provision solution than contractors. Consequently, operational solutions are not frequently optimised.

Both partners considered that the contract lacks flexibility, particularly to resolve unforeseen actions. For example, the contract does not mention that the private partner is responsible for exceptional lighting events such as the National Day or the “Night of the Stars”. So far, the private partner accepted to support these costs. However, he would like to open a special account for financing contingencies that were not anticipated and to introduce information disclosure for this account in order to preserve the stability of the agreement.

The public person in charge of following the contract was satisfied with the service quality. However, he was sceptical about the length of the contract. Even if the best technology available were selected[8], several technological changes may affect street lighting system and the actual contract may create a lock-in effect.

---

[6] Lights can be shut down in streets that do not need to be lighted in the middle of the night.
[7] The competitive dialog helped the laureate to improve its initial offer. His first proposal was to renovate 62% of the candelabra over a period of five years. In addition, at the end of the twenty years contract, only 88% of the Park would have been renovated.
[8] At this time LED technology was not considered as the most interesting option. It was twice as expensive as other technology available. Moreover, there was a lack of feedback studies for LED.

4. Discussion

The main objective of this paper was to understand why energy performance contracting was dominant in public lighting projects following a PPP procurement process and frequently omitted in building projects. To answer to this question, it appears first necessary to compare the complexity of EPC for buildings and public lighting. The five aforementioned dimensions can be examined: design, works, operation and maintenance, project financing, and measurement and verification.

Design: design is usually integrated in order to achieve higher energy savings. Lots of data are frequently missing in these types of projects even when the preferred bidder is selected. Time and money spent for data collection (information on buildings / current state of street lighting) are probably similar. However, dynamic modelling and simulation are more complex for buildings since the users (operational hours, behaviours…) have a strong influence on the results. Conversely, user will not interfere with the operation of street lighting system. Moreover, architectural issues are omnipresent in building projects but limited for street lighting.

Works: in both cases, it is necessary to coordinate a large number of subcontractors. Before and during the works, communication with the residents / the users of the buildings is a key action. In the case study, technologies used during the refurbishment of street lighting were innovative. Moreover, 70% of the park was renovated over a three year period. All these elements increased the complexity of the works. The implementation of a centralised control station appears as complex for buildings as for street lighting systems.

Operation and maintenance: in the case of public lighting, it is a standardised process. Unforeseen events are limited (e.g.: light time can be anticipated for the length of the contract). In buildings, it is harder to anticipate the evolution of the activity. For example, occupancy may vary according to the activity from one year to the other. Thus, uncertainty is stronger.

Project financing: there is a large spectrum of financial arrangements. Complexity varies from one project to the other. Apparently, it is as complex for buildings as for street lighting. However, the risk supported by the financing party is probably stronger for buildings because of the frequent gap between predicted energy performance of buildings and measured energy use once buildings are operational.

Measurement and verification: establishing the baseline is probably the most difficult task of EPC for buildings. The conceptual framework published by the U.S. Department of Energy (2015) for quantifying the savings resulting from energy efficiency equipment, improved operation and maintenance, is complex. Even if the steps are well defined, each item is subject to interpretation and several options are available. The public lighting project presented in this paper does not reflect such a high level of complexity.

Table 3 summarises complexity of EPC projects in the cases of street lighting and buildings.

Table 3: Complexity of EPC: public lighting versus buildings

Dimensions	*Level of complexity on a scale going from 1 to 5*	
	Public lighting	*Buildings*
Design	*3*	*5*
Works	*4*	*4*
Operation and maintenance	*2*	*5*
Project financing	*3*	*4*
Measurement & Verification	*1*	*4*

According to table 3 based on the author's experience with EPC in buildings (Bougrain and al. 2014) and the case study, street lighting projects integrating design, works, operation and maintenance, appear much less complex at the operational level than building projects. The absence of users who interfere with the operator and the predictability of most events occurring during the life of the contract, limit the risk. Moreover, the codification of the tasks and the measurability of outcomes are easier to implement. Thus, the control is more effective. Formal contracts seem adapted. Conversely, uncertainty is strong for EPC in buildings. Actions performed by private partners such as ESCO, are difficult to monitor. Users can adopt opportunistic behaviour. To mitigate these aspects, cooperation based on trust is essential for the success of a project.

The limited complexity of street lighting projects at the operational stage, probably explains why these projects represented about 40% of partnership contracts signed by local authorities (table 2). The paradox is that complexity was frequently cited by public authorities to justify PPP for street lighting. Conversely, the high level of complexity of EPC for buildings in operation and the uncertainty attached to this contract, explained probably the infrequent use of EPC in building projects.

5. Conclusions

The case study indicates that EPC for street lighting are very complex during design and construction phases. This complexity decreases when one moves downstream to the operation of the public network. This is due to a diminution of uncertainty: most events having an impact on the performance of the network in operation are predictable. Conversely, EPC in building projects tend to face unforeseen events during the operation: cooperation between occupants and operators is subject to tensions; protocols to measure and verify energy consumption are standardised but their implementation is still complex. This difference of complexity has an impact on the governance of each project. While pure contractual relationships may be adapted to EPC in street lighting projects, relational governance needs to be introduced in EPC for buildings. Trust can compensate the uncertainty surrounding these projects.

By investigating only one case study, the research has limitations. Further research is required to extend applications to this field. It would be interesting to examine how complexity evolves over time and impacts on governance.

Life-Cycle Economics of Rentable Prefabricated School Facility Units in Municipal Real Estate Procurement

Jaakko Vihola and Harry Edelman

Tampere University of Technology, Finland
jaakko.vihola@tut.fi

Abstract

The purpose of this paper is to study the economic feasibility of rentable prefabricated spatial units as a part of the public real estate procurement strategy. Ensuring the resource effectiveness of the municipal real estate procurement is a matter of great significance. In 2013, the gross investments of the Finnish municipalities were approximately 4.7 billion euros from which the investments on real estate were 1.7 billion euros. Thus, the investment decisions should be made based on thorough life-cycle analysis. However, the prevailing practice of public real estate procurement weights strongly on initial costs.

Recently, there have been indications of interest toward industrially produced spatial units. Rapid product delivery times combined with the spatial flexibility provided by the systems can be considered as the main benefits when compared to more traditional forms of construction. Also, the diminishing quality risks made possible by the controlled facility environment in the production phase can be seen as a major advantage. Studied business model – which relies on renting – helps to transfer the risks related to functionality of the building from the municipality to the unit provider. The research hypothesis is that using rentable prefabricated spatial units helps municipalities to avoid costs related to difficulties in predicting future space requirements.

School properties where chosen for the analysis because of the ongoing public debate considering, for example, health hazards caused by mould and moisture damage occurring in this type of buildings. Net present value (NPV) method was used to compare the municipal life-cycle costs of two school property investment alternatives in Finnish context. The comparison was made between municipality developing and owning a school property and renting the wooden spatial units needed.

The results suggest that different kinds of municipalities can benefit from prefabricated rentable spatial units. The feasibility of spatial modules improves compared to the property built using traditional methods the more the amount of students fluctuates during the analysed time period. Additional benefits include the reduced need of school transportation as well as enhanced social cohesion made possible by children attending the school in local neighbourhood together with friends from the same area.

Keywords: Prefabricated spatial units, public real estate procurement, school facilities, municipal economics, life-cycle economics

1. Introduction

Enterprises should always aim to deliver products that meet the customer's needs as well as different legislative requirements as cost effectively as possible (Asiedu, 1998; Janz and Westkämper, 2007; Niazi et al., 2005). Similar thinking can be extended to the public sector and its services, such as education facilities or even entire residential areas. Efficient procurement practices are playing an essential role when striving to meet these goals. Both in the private and public sector, different investment options should always be evaluated using proper tools to guarantee as effective use of resources as possible. This particularly applies to real estate developments since those are recognised as capital heavy long-term investments. Thus, municipalities should be long-sighted when analysing the economic outcomes of these projects.

Recently, there have been indications of interest towards rentable industrially produced spatial units. Rapid product delivery times combined with the spatial flexibility provided by the systems can be considered as the main benefits when compared to more conventional building methods. In addition, the diminishing quality risks made possible by the controlled facility environment in the production phase can be seen as a major advantage. Studied business model – which relies on renting – helps to transfer the risks related to functionality of the building from the municipality to the unit provider. The amount of modules can be swiftly adjusted when there is a change in space requirements, for example, because of demographic changes in the area. Aforementioned leads to the following research hypothesis: Using rentable spatial units helps municipalities to avoid costs related to failures in predicting future space requirements.

In Finland, the school properties have been a topic of public debate in the past couple of years. According to Reijula et al. (2012) 12–18 % of the schools and day cares in Finland are affected by considerable moisture and/or mould damage. Because of this 172 000–259 200 children could be exposed to different health hazards. When thinking of how to replace the school properties that are damaged beyond the renovation threshold, the municipalities are forced to make a decision between renting and owning new properties. The economic impacts should be carefully studied especially when the population of the school-aged children in Finland is predicted to decline rapidly in the future (Official Statistics of Finland (OSF), 2015a). Thus, owning of a permanent solution with possible low utilisation rate in the near future is questionable to say the least.

In this study, the net present value method is used to compare the life-cycle costs of two different kinds of school property investment options from the viewpoint of municipality: First, where a municipality invests to a property which is built using traditional production methods mainly relying on prefabricated concrete sandwich wall elements and hollow core concrete slabs, and second, where the municipality rents the spaces required from the manufacturer of wooden spatial units. What makes this study unique is the fact that it is the first of its kind to combine the predictions of the student population development and the cost data of municipal real estate procurement and thus providing evidence how the variation in the demand of space over time impacts on the economic equation. The next section covers the relevant literature considering public real estate procurement and prefabricated spatial units. In the third section, the data for the analysis as well as applied research method are described. The fourth section presents the results of the LCC-calculations carried out. The final chapter includes conclusions and discussion about the relevance of the results as well as underlines the need for future research.

2. Background

It has been estimated that in 2011 the total expenditure of EU member states on education was on average 5.25 % of their GDP respectively. In Finland, the government carries an essential role in providing educational services thus the corresponding number is a bit higher being 6.76 % (Eurostat, 2015). In 2013, the investments of Finnish municipalities were approximately 4,7 billion euros from which the investments on real estate were 1,70 billion euros (Finnish Ministry of Finance, 2015). It is safe to say that municipal real estate procurement plays a major role from the viewpoint of national economy.

Statistics Finland has presented a projection that the population of children that fall into the category of compulsory education (aged 7–16) will decline rapidly in the upcoming decades *(Figure 1)*. The estimation was made based on the assumption that the birth rate remains constant in the future and the mortality continues to decline in a similar fashion as when comparing the data from 1987–1991 and 2010–2014. Migration is assumed to be 17 000 persons per year between 2016 and 2065. (Official Statistics of Finland (OSF), 2015a.) However, the areal differences in population development should not be overlooked. The demand for educational facilities is likely to continue to increase in the centres of growth and decline elsewhere.

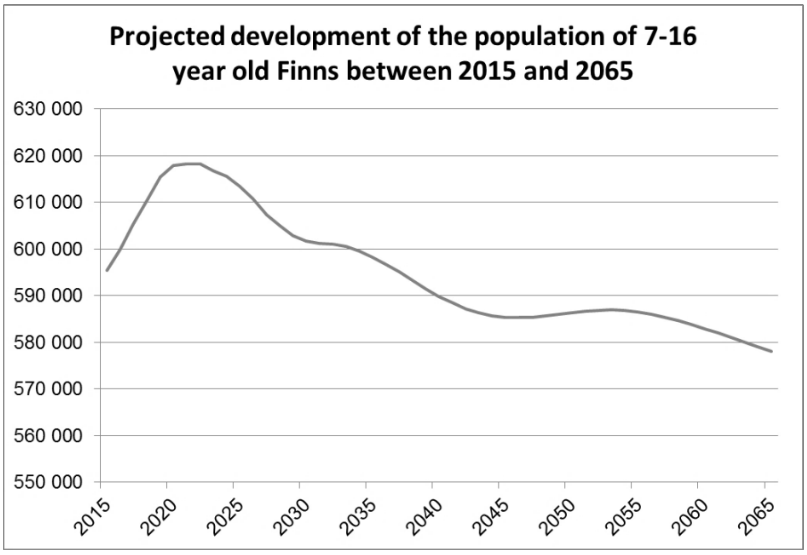

Figure 1: Projection of the development of the amount of children between 7-15 years old in Finland between 2015-2065 (Official Statistics of Finland (OSF), 2015a).

The amount of schools owned by the Finnish municipalities has declined rather rapidly since 2005 *(Figure 2)*. In 2005 Finnish municipalities owned approximately 3 300 school properties and that number has decreased to 2 400 by 2014. However Due to the increase in unit size of new school and tendency to close down the smaller units, this statistic can be deceiving because it does not take into consideration the actual volume of school buildings.

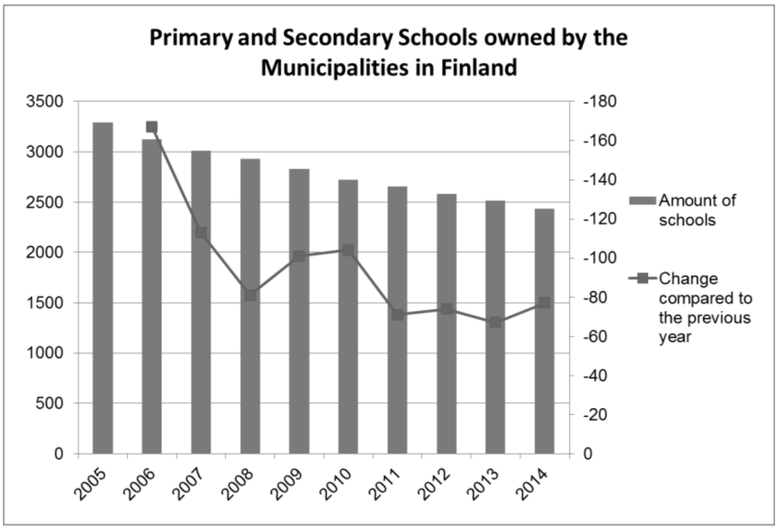

Figure 2: Primary and secondary school buildings owned by the municipalities in Finland between 2005–2014. The line graph presents the annual change (vertical axis on the right).(Official Statistics of Finland (OSF), 2015b)

Public procurement has been covered from many different angles in the existing body of literature. Most countries have a strict legislation considering public procurement of services and goods. Public tendering procedures have been a predominant mechanism for granting construction contracts in municipal sector. Usually the choice between the bidding contractors is made weighing strongly on the tender price. However, there are some studies showing that this practice leads to lacking quality and prolonged project deliveries (Cheng et al., 2000; Drew and Skitmore, 1997). Because public procurement is responsible for significant share of demand of goods and services, it is often seen as major source for potential innovations (Aho et al., 2006; European Comission, 2005; HM Treasury, 2004). However, Edler and Georghiou (2007) argue in their article how despite public procurement representing a key source of demand for the firms, for example, in construction, health care and transport industries, the potential of using public procurement for source of innovation has been largely ignored conceptually as well as in practice.

Environmental and sustainability related aspects of prefabricated buildings are well documented. Jaillon et al. (2009) investigated in their study how utilising prefabrication in building construction could help to mitigate the growing problem of building waste generation in Hong Kong area. They found out that the average waste reduction level was about 52 % compared to the conventional on-site construction projects. Bonamente et al. (2014) used LCA approach to model carbon and energy foot prints for different size buildings. The results indicate that the main environmental impacts arise from the operational phase of the buildings. Similar results were found by Faludi et al. (2012) who studied the life cycle impacts of a 5000 ft^2 prefabricated commercial building constructed in San Francisco. However, it was also stated that in the case of nearly zero energy buildings impacts from manufacturing are the most dominant. Pons and Wadel (2011) concentrated specifically on the environmental impacts of prefabricated school buildings in Catalonia. Using simplified LCA modelling, they compared the CO_2-emissions of four technologies; non-prefabricated building technologies as well as prefabricated school facilities made out of wood, steel and concrete. The results show that prefabricated solutions have lower environmental impacts through analysed time period. However, according to the study there is still room for improvement in the processes to further reduce the CO_2-emissions and especially the waste generation related to manufacturing and recycling.

The economic literature considering prefabricated spatial units is very limited. The report of National Audit Office (2005) claims that in British context construction projects carried out using modern methods, such as modular spatial units, are usually more expensive than the ones applying the more conventional methods. However, there is an overlap in the price ranges thus in certain conditions modern techniques could prove to be more cost effective. Pan et al. (2005) argue in their study which is based on survey of the top 100 housebuilding firms in UK that the cost savings of the off-site manufacturing are achieved, for example, in the areas of reduced risks and maintenance costs, shorter construction times and cost certainty.

This study contributes to the existing body of literature by being the first to focus on the municipal school property investment in Finnish context by combining the official cost data from various sources and the student population projection provided by Statistic Finland. The result is the most comprehensive analysis yet regarding the subject and can be used as a starting point when aiming for decision-making based on facts in the field of public real estate procurement.

3. Data and Methodology

In this paper, life-cycle cost (LCC) analysis is carried out to compare the economic feasibility of two different educational facility investment alternatives from the perspective of a municipality. The analysis was made between renting a school property built using prefabricated spatial modules, and the traditional alternative, in which a municipality invests to a new property and owns a building after development is finished. The analysed investment alternatives are not based on real-life counterparts. However, the cost data used in the analysis is gathered from different official sources. The main purpose is to provide information about the economic feasibility of rentable spatial units compared to more conventional method of construction by taking into account differing costs of the investments throughout their life-cycle. Also, the presented approach makes it possible to figure how the changes in the student population impact on the economic feasibility of the studied alternatives.

3.1 Data

For the purposes of the LCC calculations the data was acquired from various official sources to perform a comparison between the studied investment alternatives. The values of different variables and the data sources are listed in *table 1*.

Table 1: The municipal expenditures of the analysed investment alternatives.

Municipality invests to a new school property			**Municipality applies rentable prefabricated spaces**		
Variable	**Value**	**Source**	**Variable**	**Value**	**Source**
Amount of students	250/214	Official Statistics of Finland (OSF), 2015a	Amount of students	250/214	Official Statistics of Finland (OSF), 2015a
Required floor area	4 500 m^2	Finnish National Board of Education, 2012	Required floor area	4 500 m^2	Finnish National Board of Education, 2012
Investment cost	2 308 €/m^2	Haahtela and Kiiras, 2015	The costs of foundations and utilities	103 €/m^2	Haahtela and Kiiras, 2015
The cost of maintenance	8,2 €/m^2	Lonka et al. 2012	Transportation and installation	250 €/m^2	Parmaco Ltd., 2015
The annual growth rate of real maintenance costs	2,8 %	Official Statistics of Finland (OSF), 2015c	Monthly rent	14 €/m^2	Parmaco Ltd., 2015
Annual inflation rate (15 year average)	1,8 %	Official Statistics of Finland (OSF), 2015d	Annual inflation rate (15 year average)	1,8 %	Official Statistics of Finland (OSF), 2015d
The annual cost of technical deterioration	2,3 % of the investment cost	Nippala et al. 2006	The annual real increase of the rent	1,2 %	Parmaco Ltd., 2015

City of Kouvola was chosen as the location for the theoretical example for a school facility investment. Kouvola is situated in southeast Finland about 140 kilometres northeast from the Finnish capital Helsinki. In the end of 2013, the population of Kouvola was 86 926. Kouvola was chosen for the study area because in 2014 a school for approximately 250 students situated in the city was closed down. Another reason for the selection is the fact that according to Statistics Finland the population of the city is declining (Official Statistics of Finland (OSF), 2015e) which supports the assumptions made in the analysis. All of the expenditure variables are presented in the current price-level of Kouvola region.

Only the costs differing between the two investment alternatives were taken into account. In Finland, the technical quality of the new production practically always follows the requirements set in the part D3 of the National Building Code (Finnish Ministry of Environment, 2011). It defines the minimum requirements considering the energy efficiency of new buildings. Thus, the specific heating energy consumption (kWh/m^2) can be assumed to be similar between the two studied alternatives. When combining this fact with the predominant position of the district heating in the Finnish building stock, the utility costs in the both alternatives are very similar and thus are omitted from the analysis. Land value is not considered in the analysis based on the fact that comparison is made between two exclusionary investment alternatives for the same geographical location. In both cases, the floor area of space required is expected to be the same 15 m^2/student. The main differences between the investment alternatives are the large initial capital cost and the cost of maintenance and technical deterioration included in the alternative where municipality invests to a new school property. The costs of maintenance as well as the cost of deterioration are included in the monthly rent in the second alternative. However, also in the case of rentable spatial units there are some initial construction costs including the building of foundations and surrounding utilities as well as the costs of transportation and installation of the units. The cost information regarding the rentable spaces was provided by Parmaco Ltd. (www.parmaco.fi) which is one of the few manufacturers in Finnish real Estate market producing and renting spatial units aiming to reach similar architectural and technical quality as more conventional developments.

In this study, the residual value of the investment alternatives was ignored. This is mainly due to the fact that if municipality procures the spaces using the renting model the ownership of the modules stays on the manufacturer who will reclaim them after the service agreement ends (if there is no redemption rights clause in the contract). In the case of municipality developing and owning a new facility, the residual value is really hard to define. Technical value based on the age of the building can be quantified using various methods but the specific characteristics of education facilities make this problematic. Large school facilities are not often appealing from the perspective of real estate investors. Usually they require significant amount of alterations to modify the spaces to support other possible activities. In the case of demolition, residual value can even thought to be negative if the costs of the demolition process and waste management are taken into consideration.

3.2 Net Present Value method

Net present value method (hereinafter referred to as NPV) can be used to estimate the life-cycle costs of the investment alternatives. The NPV method is based on the time value of money, meaning that a cash flow in the future is less valuable than an identical cash flow today. The two most central reasons behind this phenomenon are inflation/deflation and a simple fact that a present cash flow can be invested immediately to earn future returns, whereas a future cash flow cannot be invested yet. The NPV method takes the time value of money into consideration by discounting the future cash flows by an appropriate discount rate. The mathematical form of the NPV equation used in our model can be written as follows:

$$NPV = \sum_{t=0}^{n} \left(\frac{Expenditures_t}{(1+r)^t} \right) \tag{1}$$

Where: t = cash flow period
r = the chosen discount rate
n = calculation period

In the model the cash flow period (t) is one year, whereas the analysed calculation period of a development project (n) is 26 years. Choosing a proper discount rate (r) is one of the most crucial elements in any type of medium- to long-term investment calculation. The discount rate describes the yield requirement for the investment, including the perceived risks, capital costs as well as desired profits. As a rule of thumb, the minimum discount rate should be at least high enough to cover the financing costs of an investment. A high discount rate gives more weight to cash flow events at the beginning of the analysed life-cycle. Thus, usually investments with low initial capital costs seem more tempting when using high discount rates. Instead, the lower the discount rate, the more the impact of the cash flow events occurring further in the future will have on the results of the analysis.

There is an extensive academic literature on the uncertainty related to public investments and selection of a proper discount rate (e.g. Arrow and Kruz, 2013; Arrow and Lind, 2014). Woodward (1997) states in his article that the appropriate discount rate in LCC analysis varies from 3 percent to over 20 percent depending on the nature of the investment and investor. For the purposes of this analysis, a real discount rate of 5 percent is used. A real discount rate does not include inflation/deflation, whereas the so-called nominal rate does. Whenever a real discount rate is used, the cash flows discounted must be presented in real values as well. The utilisation of real rates and costs is chosen because it is really hard to predict the inflation for long calculation periods. The significance of this matter grows the longer the calculation period is.

4. Results

The economic feasibility of school facility investments was studied comparing two alternatives: First, where a municipality invests to a property which is built using conventional construction methods, and second, where the municipality rents the spaces required from the manufacturer of wooden spatial units. In addition, two alternative student population development scenarios were studied. One where the amount of students stays constant through the studied time period and other where there is a decline in student population. The decline was modelled based on the estimation presented by Statistics Finland.

The results based on the calculation scenario where the amount of students is assumed to stay constant throughout the calculation period (2015–2040) are presented in *Figure 3*. It is noteworthy that the renting model does not include costs for the first year of the studied time period. This is based on the assumption that after the foundations and other preliminary works are finished the modular building system is really fast to put together. However, when building using more traditional methods, the development will take at least a year for the project of this scale. From the figure can be seen that the cumulative discounted costs of the renting model by pass the ones caused by owning the property in 2037 (22 years after the start of the development). In other words, if the purpose of the municipality is to own and use the property longer than 22 years it is more cost effective to develop and own the property. Alternatively, if the strategy is to keep the property only as long as the students can be located to other facilities in the area and the required time is shorter than 22 years the renting model will be a better choice from the viewpoint of economics.

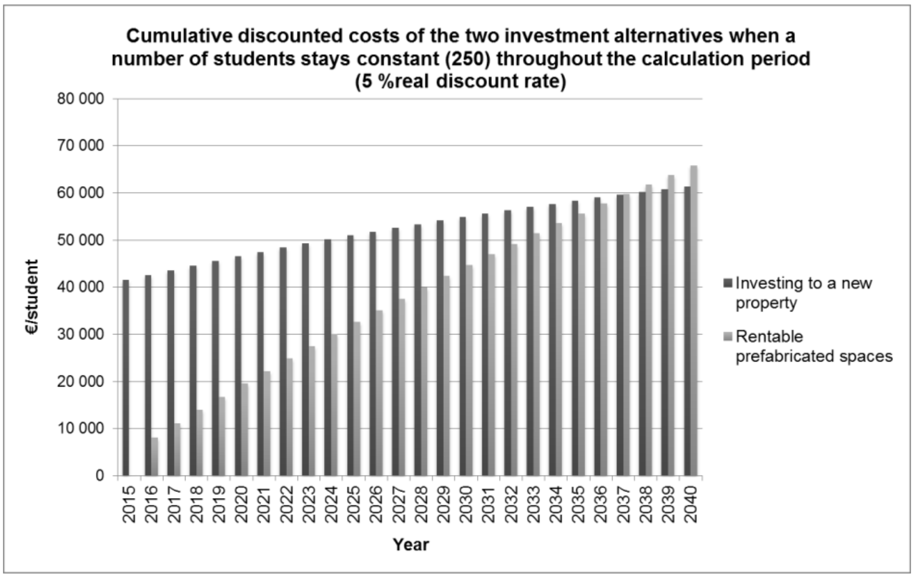

Figure 3: Cumulative discounted costs of two studied investment alternatives assuming that the amount of students stays constant during the calculation period.

One benefit of the rentable prefabricated modules is the fact that the system is spatially very flexible and responses well to changes in space demand. The calculation results presented in Figure 4 support this claim. This scenario is based to a projection made by Statistics Finland about the population development of school-age children in Kouvola, Finland. In 2015, the student population is assumed to be 250 and according to the projection it decreases to 214 by 2040. In addition, the amount of spatial units is adjusted in every ten years (2024 and 2034) by removing the units not needed anymore because of the decline in the student population.

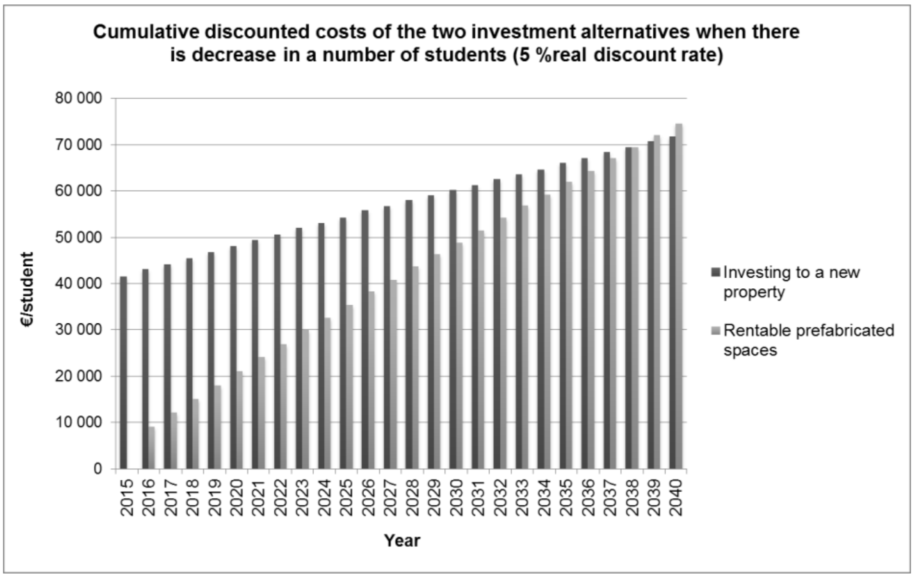

Figure 4: Cumulative discounted costs of two studied investment alternatives assuming that the amount of students declines during the calculation period according to projection made by Statistics Finland.

By comparing the previous two figures it can be seen that the decline in the student population favours the rentable spatial units because of the system's ability to adapt to a new situation. The break-even point moves to year 2039 which means that that renting the facility is now more profitable if municipality plans to own the property 24 years or less. It should also be noted that the selection of the discount rate affects a great deal to the results. The higher the discount rate, the more it favours the renting model. This is due to the fact that high discount rates favour the investments with low initial cost, and the significance of the future renting costs diminishes.

5. Conclusions and Discussion

It is foreseeable that different kinds of municipalities can benefit from prefabricated rentable spatial units. The results presented in this paper suggest that rentable prefabricated spatial units should be considered as an option especially in municipalities that have an uncertain future and thus will have a decrease in population of school-aged children in forthcoming decades. The same phenomenon is present also in growing cities where the amount of children may vary drastically by city districts. The feasibility of rentable spatial units improves when comparing to a property built using traditional methods the more the amount of pupils fluctuates during the analysed time period. Also it is worth mentioning that avoiding the unnecessary transportation of children brings many economic benefits, reduces the environmental impact, and may even enhance social cohesion when the children may attend the school in local neighbourhood together with friends from the same area.

It should be noted that the holistic economic analysis considering the procurement of any public construction project is far more complicated issue than just an LCC-calculation covering the variables related to building and maintaining properties. Every project is its own unique entity requiring customized analysis to determine the best performing procurement method. Regarding the educational services, there are many real-life cases where municipalities have tried to achieve budgetary savings by closing out schools and locating the students to other schools in the region. Usually the savings have not been reached because of the analyses are not including all of the externalities caused by the change. For example, closing down a school usually leads to costs in other areas such as transportation, re-establishing the teaching groups elsewhere, the necessary spatial modifications in substitute school, lost state subsidies, etc. Evaluating different alternatives is a complicated task. However, because of the long lasting effects and capital heavy nature of these investments, the tools and decision-making should be approached with the significance of the matter in mind.

One interesting, yet underexplored, area is so-called hybrid-models where permanent parts of the property are complimented with the prefabricated spatial units. This would enable to capitalize on the benefits related to both systems. This kind of system when in balance would make the use of the cost effectiveness of conventional construction methods and the spatial flexibility of prefabricated spatial units. However, if the Finnish municipalities continue to rely heavily on owning the public properties and procurement procedures emphasising strongly the role of the initial investment costs, the focus should be on flexible designs where the alteration of use can be carried out with minimal changes leading to increased resource effectiveness.

Water Gaps Connecting Neighbours from Conflict to Co-operation by Applying Scarcity Index

Mohamed Asheesh
Oulu University of Applied Sciences, Finaland
mohamed.asheesh@oamk.fi

Abstract

According to the latest reports of United Nations, the biggest challenge facing the world at the present and in the next decades is water scarcity. Trans-boundary water resources from history to present either lead to cooperation or to confrontation and conflicts.

For the last six decades, it has not been possible to solve the Arab-Israeli conflict, and the water issue has been raised as one of the keys for solving the conflict or having a successful discussion.

The history of the water conflict in the Middle East began by the foundation of the Israeli state in 1948. Since that time Israelis have tried to secure the state water supplies using different water resources in the area. The rapidly growth of the driving forces (Nexus) has become a source of numerous conflicts with their neighbours.

The whole area has suffered from water shortage and unsuccessful managing of the water resources. Palestinians, Israelis, Jordanians, Syrians and Lebanese are sharing the major part of their water resources, the Jordan River and the aquifer of the West Bank and Garza Strip being the main sources of water resources for Israelis and for the Palestinians. Dividing the land will not be a solution to water gaps. It is likely to make the situation even worse.

Several methods and tools have been developed worldwide to assist the riparians to manage their own shared water resources, part of which are technical and other social -political methods. Scarcity index is one technical numerical method developed to assist the parties to allocate the shared water resources and to assist on recovering the water gaps. Based on the mentioned methods numerous agreements have been made and discussions have been held between the riparians to achieve peace and co-operation. Some of them have been implemented, the other remain open due to the political changes in the area.

Keywords: modelling trans-boundary water resources, water conflict, water balance and scarcity, Middle East water

1. Introduction

Worldwide water resources are unevenly distributed and they are generally scarce in arid and semi-arid zones such as the Middle East. Lack of water, growth of tensions, distrust as a consequence of poor relations, use of force to solve conflicts and inefficient management and use of water resources are the problems besetting water resources and the Arab-Israeli shared natural resources in particular.

This paper aims at contributing to resolve the complex relationship between riparian parties resulting from mutually shared and limited water resources in general, with special focus on the Israeli-Palestinian shared water resources.

The specific purpose of the paper is to find sustainable ways to evaluate and allocate trans-boundary water resources and to determine the scarcity of water resources in the Israeli-Palestinian area.

This paper refers to a model for calculating and evaluating the water scarcity index for the present as well as for the long-term future based on analysing the rules of the international water law and the role of the United Nations in sharing and allocating the shared water resources. The computation is based on evaluating the expected demand as a consequence of population growth.

This scarcity will increase with time due to the rapid population growth, drought, as well as other constraints. With the expected population growth the gap will be approximately some 40 percent in the Palestinian and 60 percent in Israeli areas by 2020. There is an urgent need to maintain a balance in water use between the parties in the area, to reduce water scarcity, as well as to bridge the water gaps.

A joint vision based on sustainable development is formulated for the application at hand as well as alternative scenarios. The one based on joint cooperation is selected. For implementing this scenario, alternative strategic means are presented. They include especially minimizing water use, re-using the water, looking for new options for increasing the total number of water sources, and strengthening the cooperation between the parties. To support the developed model, integrated water resource management, building of institutions and development of human resources are investigated and some alternatives are suggested.

Since the water scarcity around the world can be a result of lack of accessibility, water quality deterioration, fragmentation of water management, decline of financial resources, lack of awareness by decision makers, and endangering world peace and security. The Palestinian and Israeli water conflict is an example including of the two last parameters.

When considering the major driving forces that determine the development of the mankind and its environment, we have to first set the time scale that we want to look at. To put the analysis in the framework of sustainable development, the most appropriate scale would be one generation backward and one ahead. This scale is typically used in global assessments. In this frame, the following issues are the major driving forces:

- Population growth, especially in the developing countries

One indicator for the water scarcity based on this driving force is explained later in this paper (Asheesh scarcity index), in which the author completed his case study 2002.

- Urbanization and other patterns of migration
- Changes in climate, environment, and nature
- Economy, and human capital, technology, and industrialization.

The main question which should be asked is how we can control these forces and how the international community controlled them during the last three decades.

One driving force of the above mentioned clearly appearing currently in the whole world is the migration to Europe which is a consequence of unsustainability and lack of water resources which is related to domestic use or agriculture in which will effect food production aspects and energy need (the Nexus).

2. Water sharing and riparian rights (international and national level)

The Israeli-Palestinian Water Joint Commission (WJC) announced a joint declaration for keeping the water infrastructure out of the cycle of violence and from becoming a source of conflicts. The Israelis and Palestinians view the water and wastewater sphere as the most important matter and strongly oppose any damage to water and wastewater infrastructure. The two sides are taking all possible measures to supply water and treat wastewater in the West Bank and Gaza Strip, even in the difficult circumstances of the Intifada movement that started in 2001. The two sides wish to bring to public attention that the Palestinian and Israeli water and wastewater infrastructure is mostly intertwined and serves both populations. Any damage to such systems will harm both Palestinians and Israelis.

In order to for this effort to succeed, the joint commission works based on mutual cooperation and support of all the population, both Israeli and Palestinian. The general public is asked not to damage the water infrastructure in any way including pipelines, pumping stations, drilling equipment, electricity systems and any other related infrastructure. The two sides also call on those involved in the crisis not harm water resources, the professional teams that conduct regular maintenance or repair damage and malfunctions to the water and wastewater infrastructure. Both sides wish to take this opportunity to reiterate their commitment to continued cooperation in the water and wastewater spheres.

In the United Nations proposal for water management and international sharing of water resources declared in 2000, the right to water was one of the essentials to be achieved, right to a standard of living adequate for the health and well-being of himself and family" (Universal Declaration of Human Rights Article 25, United Nations 2000). The right was to be for everybody regardless of his/her financial status. In recognition of the absolute need for water for survival, governments should regard the quantity of clean water necessary to ensure a decent standard of living for all people as sacred. An adequate supply of water must also be reserved for preservation and natural regeneration of the environment. Priority should be given to allocating the limited water resources according to the purpose of the use (Asheesh, 2003).

In the Palestinian-Israeli case the inhabitants of Israel and the Palestinian Territories share their main sources for drinking water. The largest resource is the Jordan River. Compared to other rivers in the Middle East like the Euphrates, the Tigris or the Nile, the Jordan River is a rather modest one – in length as well as in flow. Its main tributaries are the Hasbani, Dan, Baniyas and Yarmuk. The first three rivers converge in Israel, north of the Lake of Galilee, to form the upper Jordan River. Only the Dan originates within Israeli borders. The Hasbani springs lie in the part of Lebanon that was until June 2000 incorporated into the occupied Israeli security zone in southern Lebanon, and the Baniyas water drains from the Golan Heights – a territory formerly under Syrian control and since the war of 1967 occupied by Israel (Asheesh, 2003).

A holistic view needs to be taken of the water resources problem in the Arab world including the Israeli territory. The following aspects should be considered: Water requirements are calculated on a minimum basis known as "minimum water requirement" (MWR) which is 1,200 cubic meters/year (CM/Yr). The population of the Arab world is presently nearing 235 million; the quantity of available water per person is about 750 CM/Yr, which is below the MWR. If the population reaches 295 million by the year 2020, then a person's share of water will drop to 575 CM. If the average population growth is 25 per thousand, then the water requirement will reach 295 billion CM by the year 2020, i.e., a deficit of 120 billion CM. (Tamimi 2012).

Water struggles and water resources conflict will be always the key for peace and stability in the area. Using force over water resources undermine these goals in long term. For example the Nile conflict and water allocation have been between the parties. Appeared after almost 100 years. The Kenyan government decided to build a new dam to secure their sustainable water resources and energy. The Arab-Israeli water conflict parties should learn a lesson from this case. The water issue always weave as the most difficult and changeable issue of the five conflict issues in the Palestinian and Israeli the other issues in dispute, Jerusalem, borders, settlements and refugees are not so susceptible to the same effective and often usefully politically silent solutions provided by socio-economic development.

2.1 Framework for negotiation and cooperation

It has been widely accepted that the political, economic, social, technical and environmental (PESTE) and resource problems directly affect regional and international security. Although these PESTE aspects have not been so far sufficiently incorporated into the approaches to reduce the risk of water conflict, a framework needs to be constructed that encourages scholars and policymakers to apply new tools, to set new priorities, to organize responses, to recognize water rights, share control and monitoring and portioning of water resources and to eliminate a range of environmental threats to peace and security (Asheesh 2001a). Based on the mention the main question is how a Palestinian State should approach the principles of sovereignty and cooperation over water.

In October 1994, a peace treaty between Israel and Jordan was signed which addresses water allocations, sharing of water information, and joint management policies for the Jordan River Basin. The Convention on the Non-Navigational Uses of International Watercourses based on article 6 of the treaty reads as follows:

The Parties agree to recognise the rightful allocations of both of them to the waters of the Jordan River and the Yarmouk River and Araba/Arava groundwater in accordance with principles set in Annex II of the Jordan Intelligence Agency agreement (JIA 1998).

The Parties jointly undertake to ensure that the management and development of their water resources does not harm the water resources of the other party.

The Parties recognise that more water, to meet their needs, should be supplied through various methods, including projects of regional and international cooperation.

Parties agree to search for ways to alleviate water shortage and to co-operate in the following fields:

- Development of existing and new water resources
- Prevention of contamination of water resources
- Mutual assistance in the alleviation of water shortages
- Transfer of information and joint research and development in water-related subjects.

Unless all the people who depend on the resources concerned are included in the agreements, conflicts will pertain. In particular, definitions of equitable utilisation of existing water resources must be negotiated and applied. These negotiations include discussing the priority of using the resources, like in the Israeli-Palestinian and California cases and other cases in other parts of the world, to resolve the wrestling between the demand for domestic and agricultural or urban and rural sector (Gleick 1996). The framework for cooperation will help in the formulation of criteria and prioritisation of the realisation of any of the proposed activities. As the water authority in the area is presently unorganised and the water itself is a quickly diminishing natural resource, direct involvement and efficient cooperative water administration is obviously essential and thus this factor cannot be handled separately from the technical issues.

Based on the above mentioned understanding between the both sides, the Palestinians and the Israelis, the joint water institutional framework could strengthen the management of the operation and maintenance of the shared water resources.

The precondition for formation of such a framework is that the respective parties start to base their understanding of the need to improve the water situation on trust, good faith and respecting each other’s sovereignty. In this way using the water resources may happen in a reasonable and equitable way in accordance with the rules of the international joint committees (Israelis and The Palestinians). A joint water framework may be built first through negotiations about allocation the shared water respecting the hydrological distribution of the sources (and not according to geographical areas) and second in spirit of cooperation.

In light of the above, the following joint water framework could be considered in Palestinian-Israeli negotiations over water issues. The joint institutional framework illustrates the future administration and management functions in the area (Figure 1).

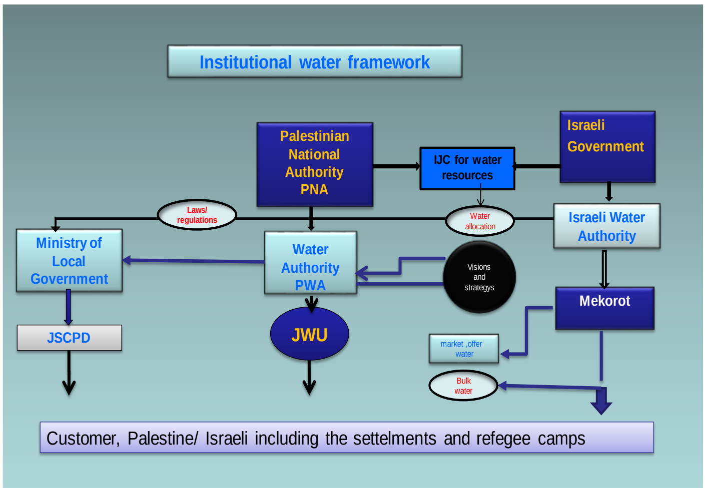

Figure 1 Institutional framework for arrangement of water resources and services

The role of the Water Authorities of both sides is to control and monitor the shared resources, since the sub roles of Jerusalem Water Undertake (JWU) and Joint Services Council Provider Department (JSCPD) to provide the services to the Palestinians side and Mekorot (Israeli water providers) to the Israeli side are essential to the framework.

The framework for cooperation should include the management of wastewater also, which poses a risk to the environment, since the groundwater lies relatively close to the surface and is easily contaminated (Nashashibi 1995). There are only a few wastewater treatment plants in the area, and the wastewater network is not large enough. Consequently, proper planning and locating of treatment plants and expansion of the wastewater network make up an important part of this research. Water re-use, which represents a new possibility to increase water resources in the area, can eventually help conserve significant amounts of fresh water, but much more research is needed to determine how water could be re-used in agriculture and industry.

According to (Kuttab & Jad 2000), three major issues concerning the Israeli-Palestinian conflict have to be analysed and ranked with regard to cooperation in water resources by the Palestinian West Bank and Gaza Strip Territories and the Israeli state.

The first issue relates to water resources that originate and are discharged completely in the Palestinian West Bank and Gaza Strip. The most obvious example of this sort is the Eastern aquifer resulting from rains within the catchment area east of the hydrological line that crosses the West Bank towards the Ghor Valley.

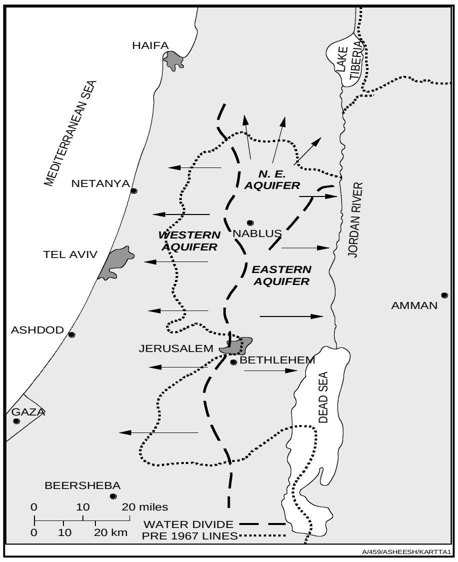

Figure 2 The hydraulic line locates the aquifer basin in the West Bank (Asheesh 2003)

The Israeli West Bank Mountain Aquifers have three general basins. The west aquifer, providing more than a half of the total yield in Israel, is called the Taninim aquifer, the second aquifer is the northern aquifer and the third one is the eastern aquifer. The last one lies on, and enters the West Bank. The second and the third aquifers as well as the most important west aquifer, qualify as trans-boundary basins, and any water distribution solution should be based on principles of sharing the watercourses under international law.

The second issue relates to the riparian waters, which flow into the Jordan River. The Palestinians in the West Bank together with Jordan, the State of Israel and Syria share these resources. Despite the absence of clear precision, there are sufficient guidelines in international law pertaining to surface water.

The third issue pertains to water resources resulting from rainfall in areas west and northwest of the hydrological line and which feed two main aquifers that are shared with the State of Israel. The major portion, about 80 percent, (Asheesh 2000) of the waters in these aquifers originates from the West Bank catchment areas.

The aquifer itself flows and actually straddles the border between the two areas with the majority of it found in the West Bank Territories. The consumption of water based on withdrawal from those aquifers (the eastern and northern aquifer) it shows that the main and the biggest share is consumed by the Israeli settlements in the West Bank area.

Since the shared water resources between the neighbours are the main issue for peace and security, the cooperation on the operation and maintenance of the water system in general is the main key in the hands of the decision makers on solving the gaps of water in the current situation and securing the demands for long term. The joint institutional water framework to joint water authorities on both sides, water Authorities which can be based on the recognizing the right of both nations and based on the international water right declared by the international water law.

3. Indicators for International Water Gaps and Water Stress

In the past 20 years many indices have been developed to quantitatively evaluate water gaps and needs. Several indicators has been made to avoid conflict and to promote the cooperation and to prevent the conflict, struggles and distrust of controlling of the water resources.

The Falkenmark indicator is perhaps the most widely used measure of water stress. Gleick (1996) developed a water scarcity index as a measurement of the ability to meet all water requirements for basic human needs. Ohlsson (2000) integrated the “adaptive capacity” of a society to consider how economic, technological, or other means affect the overall freshwater availability status of a region. The UNDP Human Development Index (HDI) is a widely accepted indicator used to assess these societal variables. The International Water Management Institute (IWMI) used a similar water scarcity assessment though on a slightly larger scale across the entire globe. They conducted an analysis that considered the portion of renewable freshwater resources available for human requirements (accounting for existing water infrastructure), with respect to the main water supply.

Indicators of physical water scarcity include: acute environmental degradation, diminishing groundwater, and water allocations that support some sectors over others (Molden, 2007). Countries having adequate renewable resources with less than 25% of water from rivers withdrawn for human purposes, but needing to make significant improvements in existing water infrastructure to make such resources available for use, are considered “economically water scarce” (Seckler et al., 1998).

Freshwater scarcity is commonly described as a function of available water resources and human population. These figures are generally expressed in terms of annual per capita water and mostly on a national scale. The logic behind their development is simply that if it is known how much water is necessary to meet the human demands, then the water that is available to each person can serve as a measure of scarcity and these human demands (Asheesh 2003) (water right) can be identified by the riparian themselves. This can be schemed and established the visions and strategies of the shared water resources (the case of the Palestinians and the Israeli shared water).

4. Water Scarcity Based on Papulation Growth (the scarcity index)

Combining the population growth with the minimum water requirement (MWR) water gaps have been calculated, Table 1 illustrated the water gaps for some of the Middle East countries. This estimation was made disregarding the impact of the Syrian civil war. Since the war started in Syria millions of Syrians escaped from their homes to the neighbouring counties like Jordan, Lebanon and Turkey, which most likely escalates the water stress in those countries.

Based on the population growth the prediction equation1 is illustrated as follow:

$$A_n = A_x\left(1 + {}^{p}\!/_{100}\right)^n$$

Equation 1

Where

A_n: number of inhabitants

A_x: Current number

P: Growth percentage

n: Prediction length

To apply the term of minimum water requirement for all parties the following calculation for water projection for 2015 illustrated in Table 1 was carried out.

Water shortage can be calculated according to water minimum water requirement illustrated in the table1. The total water requirement used in the table assumes that the riparian are using the potential water resources in equitable reasonable way. Water uses in the area are divided as follows: domestic use 120 m3/C/Y (Shuval 1994) in addition to the demand for the industrial uses is 10% 25% from the total use, and 70% for the agricultural uses. The Israelis currently are using 300 l/c/d in the settlement areas for different purposes.

Table 1 Minimum water requirement for some of the Middle East countries

Area	*Population in 2013*	*Population in 2025*	*Water resource potential (Million m3/Y)*	*Total water per capita per year in 2013 (m3/P/Y)*	*Total water per capita per year in 2025 (m3/P/Y)*	*Total MWR in 2025 (Million m3/Y)*	*Total excess or shortage (Million m3/Y)*	*Growth rate (%)*

4.1 Water scarcity and the balance of water resources based on the scarcity index calculation

Balancing of the system is accomplished by covering the gaps or preventing the depletion of water resources and monitoring the relation between the inputs and outputs of the system *equation 2 is* presenting the parameters related to the balancing the system. In the case of depleted national or international river basin aquifers, covering of gaps or controlling and stopping the flow of the shared transboundary aquifer can be an alternative to balancing the situation inside and outside the system on the national and the international level, the scarcity index is an indicator that shows developments in the water situation of a riparian country. It points out the size of the gaps that should be covered or amounts to be returned into the system in order to secure the balance between available water and water demand.

$$W_{sci} = (W_{av} / W_{tad}) - 1$$

Equation 2

Where

W_{sci}: Water scarcity index

W_{av}: Available water resources in shared basin (in the state)

W_{tad}: Total annual demands for all riparian/states

The scarcity index developed reflects the relationship between the water system inputs and outputs from the system based on population growth in a given time. The scarcity index is expressed as a shortage or gaps (expressed as percentages), as the relationship between the parameters of available water and demands as illustrated in Equation 3. The main element of the equation is population growth, which determines all demand parameters in the water sector.

$$Wsci = \left(\frac{\alpha}{\left(\left[\frac{100}{100-p} \right] \beta \exp^{\lambda \Delta t} (\varepsilon + \gamma + \delta) \left(\frac{100}{100-\kappa} \right) + h + b \right)} \right) - 1$$

Equation 3

Where:

W_{sci} : Scarcity index

α: Input into system (A or B riparian)

ε: Annual domestic demand (m3/c/y)

γ: Demand for green areas (m3/c/y), it depends on population growth

δ: Demand for irrigation (m3/c/y)

λ: = Ln (1+r), population growth rate

Δt: Length of time for which the estimation is made, the period can be calculated as the difference between the present and the future (t-k);

β: Population

t: Present time

h: Yearly evapotranspiration of water, depends on climate of country

b: Water needed to maintain the environment, depends on the length and depth of the water body

k: Estimated losses

p: Industrial demand as a percentage, depends on country structure, its value can be determined as 15-25 percent of the domestic demand

5. Conclusions

Over more than 30 years in conferences and seminars worldwide, experts have been talking about managing the international water resources and improving the cooperation between the riparian parties. All these talks and papers remain a theory. Still the United Nation agreements and conventions remain on paper and not binding any party. The riparian parties are not learning the lessons and there is more and more suffering due to water gaps and water stress. In this paper two Mathematical methods were illustrated to help the parties in allocating the shared water resources, the two methods, the minimum water requirement (MWR) and the scarcity index, are just a tools developed to help the riparian to manage their national water resources also.

While the MWR method gives an indication of the shortages for a certain period, the second tool describes in detail the water gap and the way how to save water and how to control and recover the gap.

Since these two methods and worldwide others methods developed to assist the international community to avoid conflicts but few of those riparian are considering and applying them. Several of the riparian are using water as a weapon and water resources as a good to solve country economic crises in the upstream downstream cases.

In global scale a lot of tools and methods have been developed, water engineers finding them as useful tools, but unfortunately the decision makers are not understanding the means of these tools.

The International Joint Institutional Water Framework in the areas of conflict can be also one tool to push the parties for cooperation, the role of the international community as a mediator is to support the decision makers in being active to support their local water authorities to participate in the established joint Institutional Framework and as well as developing the joint capacity building programme.

Clearly, migration to Europe as a consequence of unsustainability and lack of Nexus is a phenomenon affecting the whole world currently. Water rights and international law should be followed and recognized. Cooperation between the riparian should be continued even when players at high political levels are changing. Exchanging the data related to renewable water, operation, demand and services on all levels should be continued.

Implementation of the United Nations' rules to riparian should be done to all shared water resources without any enforcement limitation.

Mediation in Construction Disputes: A Review of Turkish Case

Yiğit Beşlioğlu and Atilla Dikbaş

Istanbul Medipol University, Turkey
Email: ybeslioglu@medipol.edu.tr

Abstract

Construction contracts often become subjects of disputes, mostly as a result of multiparty, time barred and complex nature of construction projects. Construction disputes are remarkable both by their values and numbers, so it takes money and time to resolve them. Although litigation is the customary way of resolving construction disputes, alternative dispute resolution techniques have been developed to obtain shorter and better dispute resolution. Mediation, for example, as an Alternative Dispute Resolution (ADR) method is viewed as "beneficial, allowing an element of a dispute to be settled, narrowing the disputes or contributing to a greater understanding of the other side's case generally". Alternative Dispute Resolution techniques have been used in countries like UK, USA, for many years and considerable experience have been gained since then. In UK, researches reveal that construction industry is well aware of ADR methods and effectively uses them to resolve disputes. For Turkish construction sector, on the other side, ADR techniques are not as familiar as they are in UK. “Law on Mediation in Civil Disputes No. 6325”was enacted in 2012, though it has been rarely used since then, especially for commercial and construction cases. Using mediation as a dispute resolution method in construction cases is currently an unfamiliar process for Turkey; Industry professionals have little knowledge about mediation, legal professionals approach mediation suspiciously and there is limited knowledge about what could be expected from mediation in relation to commercial cases, especially construction disputes. This paper aims to find out and discuss the developments in use of Mediation as a dispute resolution method for construction cases in Turkey since enactment of Turkish Mediation Law in Civil Disputes. After a review of past literature and researches on mediation as an alternative dispute resolution method for construction industry in Turkey, cases referred to mediation since the enactment of “Law on Mediation in Civil Disputes No. 6325” has been analysed in order to find out current practice. Results reveal the fact that mediation has rarely been used by construction industry until now.

Keywords: Construction Disputes, Mediation, Alternative Dispute Resolution

1. Introduction

Alternative Dispute Resolution methods have emerged as an alternative to traditional litigation due to their ability to provide faster, cheaper and undisclosed solutions to commercial disputes. Although alternative dispute resolution methods such as mediation and arbitration have their roots in ancient laws of Middle East as old as 1800 BC (Boulle 2005) or ancient Far East approaches to dispute resolution (Özmumcu, 2011), modern usages have mainly emerged in early 20th century from USA and Western Europe. Of these methods, arbitration has provided a convenient method to dispute resolution, especially for cases that emerged from contracts related to international commerce. 1958 New York convention has offered the parties who hesitated to go to local courts for disputes arising from international contracts, a relative protection in signatory countries. (1958) Fast globalisation of international markets has been seen as a factor in parties' willingness to use ADR methods, thanks to their pragmatic character. (Tanrıver, 2006) Growth of international trade from Second World War moved away side by side with growth of usage of Alternative Dispute Resolution processes. Large expansion of capital movements and international investments after Second World War can also be seen as a catalyser for rising interest in ADR methods. (Newcombe and Paradell, 2009) Besides its advantages, arbitration process still constitutes an adversarial process and costs could be high. Gradual, stepped dispute resolution methods have been adopted to overcome these difficulties. Flexible, hybrid methods that provided cheaper solutions for dispute resolution process became popular in commercial as well as construction contracts. (Arıcı, 2012)

Turkish case has followed its Western counterparts in adopting ADR methods to find cheaper solutions for dispute resolution and prevent litigation whenever possible. In context of Mediation, a special legislation was enacted by Turkish Parliament that regulates Mediation in Civil Disputes in 2012. This paper aims to discuss use of mediation in construction disputes by comparing survey results conducted between construction industry professionals prior to enactment of law and official statistics published since enactment.

2. Way to "Law on Mediation No.6325"

One of ADR methods, used as a pre-litigation method, is mediation. Mediation has its origins in traditional Far East dispute resolution culture. Its modern use in construction contracts has emerged first in US and spread to UK (Özmumcu, 2011). It was started being used in early 1990s in UK, though its progress in construction industry has been slow until late 1990s. However, researches conducted in UK on use of mediation reveal that construction industry is now well aware of ADR methods and effectively uses them to resolve disputes. (Gould and King, 2010)

On the EU side, EU Commision has encouraged member and candidate countries towards enacting legislation concerning usage of Alternative Dispute Resolution methods in commercial disputes. In 1999, the Heads of State or Government of the Member States "called for the creation of alternative, extrajudicial procedures for dispute resolution in the Member States in order to improve access to justice in Europe". (Europa Press Releases, 2008)

On 2002, EU Commission presented a Green Paper on alternative dispute resolution in civil and commercial law. The objective of Green Paper (2002) was presented as "to initiate a broad-based consultation of those involved in a certain number of legal issues which have been raised as regards alternative dispute resolution in civil and commercial law." The paper listed the interest in ADR in European Union then, according to three main reasons; increasing awareness of methods, legislation encouraging usage of ADR methods and political priority given by EU Institutions to promote ADR methods.

In 2004, European Commission adopted its Proposal for a Directive (IP/04/1288) establishing rules on civil procedure to ensure a sound relationship between mediation and judicial proceedings. The European Code of Conduct for Mediators was launched in 2004, developed by a group of experts as a self-regulatory instrument, to deal with matters concerning issues on accreditation and appointment of mediators. The Code of Conduct (2004) stated that it was aimed at setting out "a number of principles to which individual mediators may voluntarily decide to commit themselves, under their own responsibility. It may be used by mediators involved in all kinds of mediation in civil and commercial matters".

On 23 April 2008, European Parliament approved the Directive on certain aspects of mediation in civil and commercial matters. Directive aimed to "facilitate access to alternative dispute resolution and to promote the amicable settlement of disputes by encouraging the use of mediation and by ensuring a balanced relationship between mediation and judicial proceedings." Directive stated that member states shall adopt necessary laws, regulations and administrative provisions into national law to comply with the requirements of the Directive.

Trends in Turkey have also evolved towards adopting special legislation regulating use of ADR methods. Although, concepts of ADR methods such as mediation, conciliation are seemed as unfamiliar to Turkish Law, Turkish Law contained concepts of compromise, settlement agreement and similar concepts in various laws. However, rather than being regulated under a special law, various laws contained provisions including these concepts. (Özmumcu, 2011)

Since 1990s, in tandem with developments in Western countries, an increasing academic interest in ADR methods could be seen in Turkey as well. Process of adaptation of national laws in compliance with EU Regulations as part of EU accession process and the ongoing academic debates on regulating ADR under special laws opened the way for the "Law on Mediation in Civil Disputes No. 6325". A commission was formed to prepare draft law and various legal sources were considered in preparation of draft. Draft law was approved in Turkish Parliament in 07.06.2012 and was enacted. Provisions of Draft Law were generally in compliance with EU Directive and before its enactment it was stated by the researchers that the Draft Law "provides the main directions for possible implementations in the Turkish construction industry". (Dikbaş and İlter, 2008)

3. An overview of "Law on Mediation in Civil Disputes"

"Law on Mediation in Civil Disputes No.6325" stresses that mediation employs systematic techniques, it is a voluntary process and requires the participation of an impartial and independent third person with specialty training. (Clause 2.1) Article 3 defines voluntariness and equality as basic principles of mediation. Confidentiality, one of the most important strengths of ADR methods when compared to litigation is dealt under Clause 4. Article 9 states that mediators are liable of carrying out their jobs carefully and impartially. Article 13 states that resorting to mediation can be done "before filing a law suit or during the course of a law suit" as long as it is done on basis of agreement of both parties. Article 15 provides the opportunity for the parties to choose their own mediation procedures. Parties shall not be bound by strict rules and procedures can be chosen on a flexible basis. Article 17 determines the circumstances when a mediation process is considered to be concluded. Under Article 18, agreement of parties is considered. In compliance with the flexible nature of mediation, no rules on the scope and form of the agreement are imposed on parties.

In respect of agreement, it is stated that unless the parties will desire the agreement to have the force of a verdict, the document will be subject to general provisions. Article 19 requires that Ministry of Justice "shall keep the register of the persons who attained the authority to mediate in private law disputes". Under Article 20, only persons who hold an undergraduate law degree with at least five years of experience are allowed to register as mediator. Article 22 determines that any person willing to register as a mediator shall receive a "mediation training". Article 33 deals with the situations when the rule of confidentiality stated in Article 4 is violated. Violation of confidentiality may result in imprisonment up to six months and prosecution of the offence depend on complaints.

4. Mediation in Turkish Construction Industry

Research conducted in 2008 by Dikbaş and İlter reveals that Turkish construction industry was unaware of the mediation as an ADR method. Findings at the time revealed that prior to enactment of Mediation Law, %85 of respondents of research have never been involved in mediation process as part of resolving disputes arising from construction contracts. On the other hand, Dikbaş and İlter point the fact that 90% of the respondents said that they would consider using mediation.

Another survey conducted prior to enactment of Mediation Law seems to support these results. According to the survey, conducted in 2010 by Gül and Acar, participants from construction industry stated that they use mediation as a dispute resolution technique between never and rarely for disputes arising in international markets and they rarely use mediation for disputes arising in local markets.

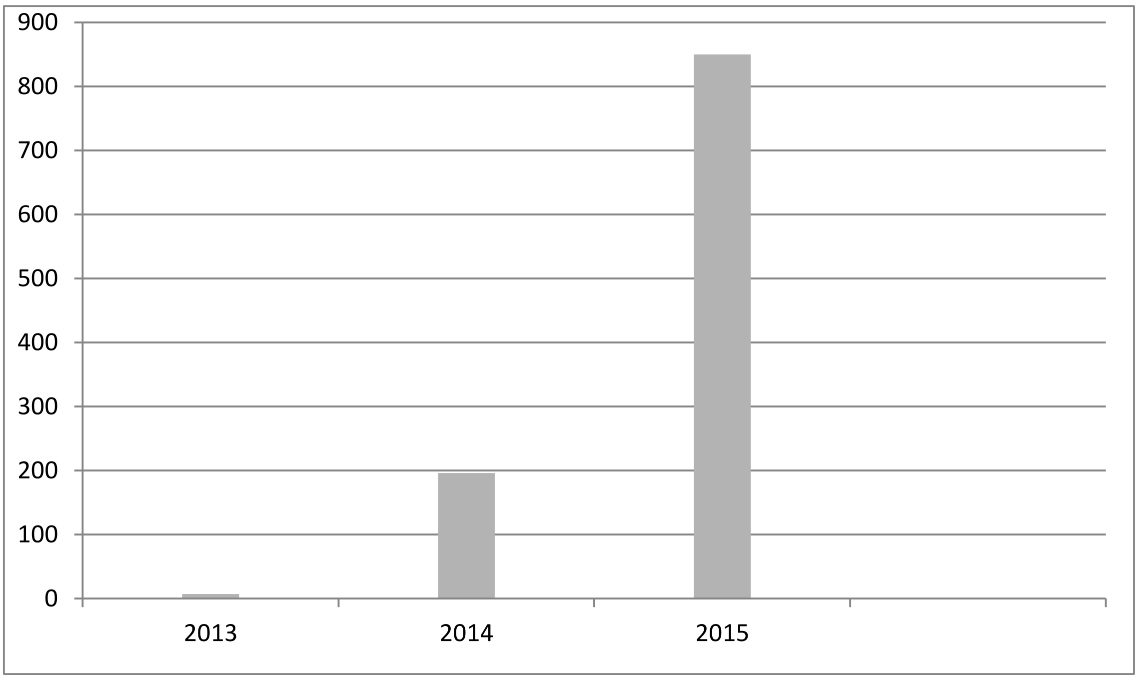
Another data obtained from construction industry professionals in 2012, by Arıcı, reveal the level of knowledge on ADR methods. Survey was conducted in 2012, in the same year with enactment of Mediation Law. According to survey, public officials working in construction projects have little to medium knowledge on mediation. For those working on contractors, knowledge of mediation seems to be between medium to high. The same survey reveals that public officials have been involved in a mediation procedure between “rarely to sometimes”. Contractors on the other hand have responded that they have been involved in a mediation process in past projects between “never and rarely”.

Findings of the surveys conducted by Dikbaş and İlter (2008), Gül and Acar (2010) and Arıcı (2012) seem in line with each other. It seems that level of knowledge has slightly increased from 2008 to 2012 while mediation experiences of industry participants have been rare.

More than 3 years have passed since the enactment of Mediation Law and Department of Mediation established under Ministry of Justice after the enactment of legislation, publishes the statistics about mediation regularly since then. Statistics reveal that in only 1053 cases mediation has been chosen as a method for dispute resolution. When compared with huge number of cases dealt in civil courts, 2.024.056 new cases were brought to civil courts while number of open cases reached as high as 3.293.090 over the year, number of disputes referred to mediation seems marginal.

Number of cases referred to mediation, on the other hand, seems to increase rapidly; only 7 cases were referred to mediation in December 2013, number increased to 196 in 2014 and 850 in 2015 until the end of October. This rapid increase may be parallel to the increase in rising number of mediators and increasing awareness in public as a result of efforts to promote ADR by using advertisements, panels etc.

Table 1: Number of civil cases referred to mediation from December 2013 to October 2015 in Turkey

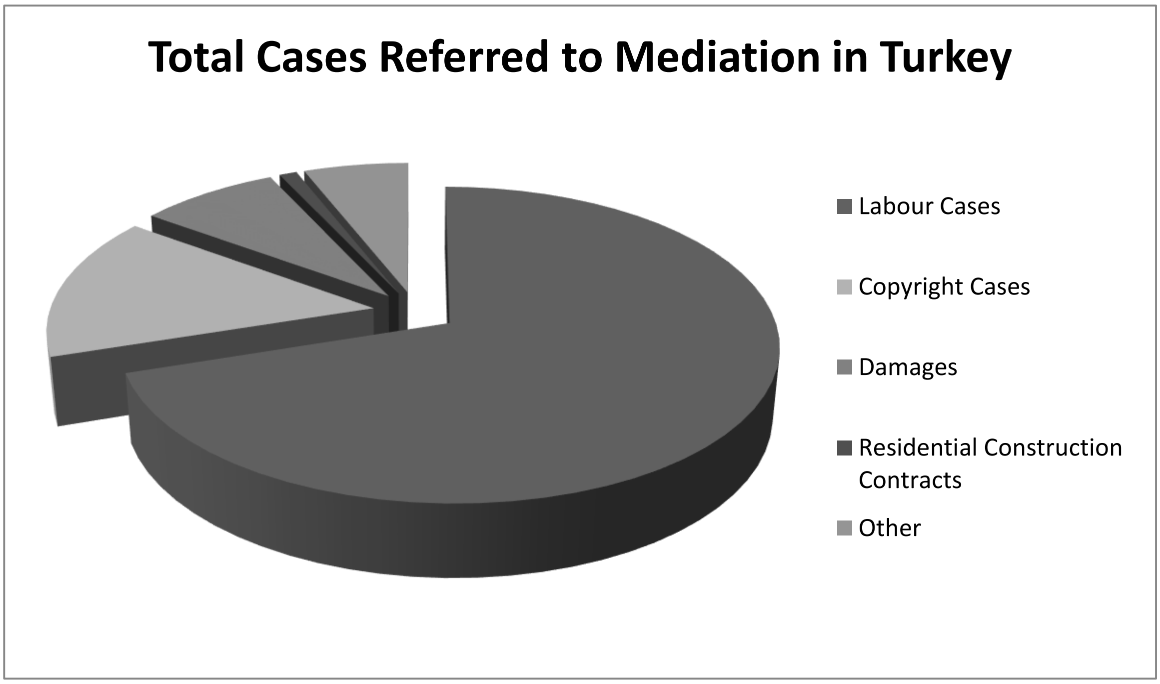


According to official statistics, construction industry hardly seems to consider using mediation until now. Number of cases concerning residential building contracts between landlord and contractors referred to mediators are only four. Of these four cases, two were referred in 2014 and two were referred in 2015. Three of these cases were resolved with an agreement between parties, while one case could not be resolved by agreement.

Statistics are published according to the subjects of cases and cases under headings "compensation" may involve disputes related to construction contracts. However, only 82 cases arising from damages were referred to mediation and this constituted an overall %8 of total cases.

Statistics reveal the fact that 70% of total cases referred to mediation were cases related to labour law and 15 % were related to copyrights. This large number of cases containing disputes arising from employment contracts might be commented as a continuance of familiar practices since the Labour Law contained provisions regarding conciliation even before the enactment of Law on Mediation in Civil Disputes.

Table 2: Distribution of total cases referred to Mediation in Turkey according to their subjects



5. Conclusions

This paper aimed at getting a balance of Turkish Mediation practice, in the context of Turkish construction industry, after the enactment of Law on Mediation in Civil Disputes in 2012. Pre-legislation researches and post-legislation statistics were compared to provide an overview of current situation.

Surveys conducted by researchers in 2008, 2010, 2012 respectively showed that Mediation practice was unfamiliar for construction industry. However, slight increase in awareness prior to enactment of legislation and positive approach of industry participants towards using ADR and mediation in future disputes provided a suitable background for future of ADR and Mediation in Turkey.

However after three years of mediation experience, an analysis of statistics reveals the fact that mediation is still an unfamiliar and unknown process in Turkey. Besides large number of cases referred to courts each year, a marginal number of cases were referred to mediators. Of these cases, construction cases remain insignificant in portion, which indicates the unwillingness or unfamiliar approach of the industry participants towards using new methods in dispute resolution.

On the other hand, rapid increase in cases referred to mediation each year, increasing awareness of society due to strong support of public bodies, time and cost problems arising in arbitration processes as well as in litigation and the trend that was followed in Western countries all point to an increased use of mediation by construction industry in future.

Housing Dispute Settlement System in Japan; Part 1 - The housing dispute settlement system and the background to the legislation

Hiroshi Ito and Masaaki Suga

Center for Housing Renovation and Dispute Settlement Support
Email: itou@chord.or.jp

Abstract

In this report, we summarize the Japanese system for settlement of housing disputes.

We will detail the background of the legislation and the establishment of the system, along with its current state and operational results.

We posted two related abstracts to WBC16. In the first abstract, we report on the system's background and processes. In the second, we discuss the operational results and present conditions of the system application.

Keywords: Housing defect, Housing dispute settlement, ADR, Legal & Technical advice, Consumer

1. Introduction

This report introduces the Japanese system for the settlement of housing disputes.

We mentioned Japan's housing situation and the need for a system for settling housing disputes. Next, we will outline the origins of the housing dispute settlement system Japan. Finally, we provide an overview of the system for settlement of the housing disputes in Japan.

We will also mention two related services that contribute to housing dispute resolution – telephone consultation and face to face expert advice that lawyers and registered architects attend.

2. Japan's housing situation and the need for a system for settling housing disputes

2.1 Japan's housing situation

From the viewpoint of the housing stock, the total number of housing units in Japan is 61 million units according to the results of 2013 survey[1] by the Ministry of Internal Affairs and Communications, Bureau of Statistics. This includes 52 million residential units, which consists of 29 million detached houses and 23 million apartments. Many detached houses and low-rise apartments, totalling more than half of Japan's housing units are wooden structures.

From the viewpoint of newly supplied houses, approximately half of the dwelling units in Japan are built by big housing companies, with the remainder built by small and medium-sized housing companies. In terms of the number of housing companies, 99% of the whole housing companies are small and medium-sized companies and 1% are big housing companies in the market.

Figure 1 shows the number of houses built in Japan[2] every year since 2000. In the 5 years after the 2007-2009 slump, which was due to the subprime mortgage crisis, 800 to 900 thousand newly units have been built. The ratio of apartments is approximately half of the total houses.

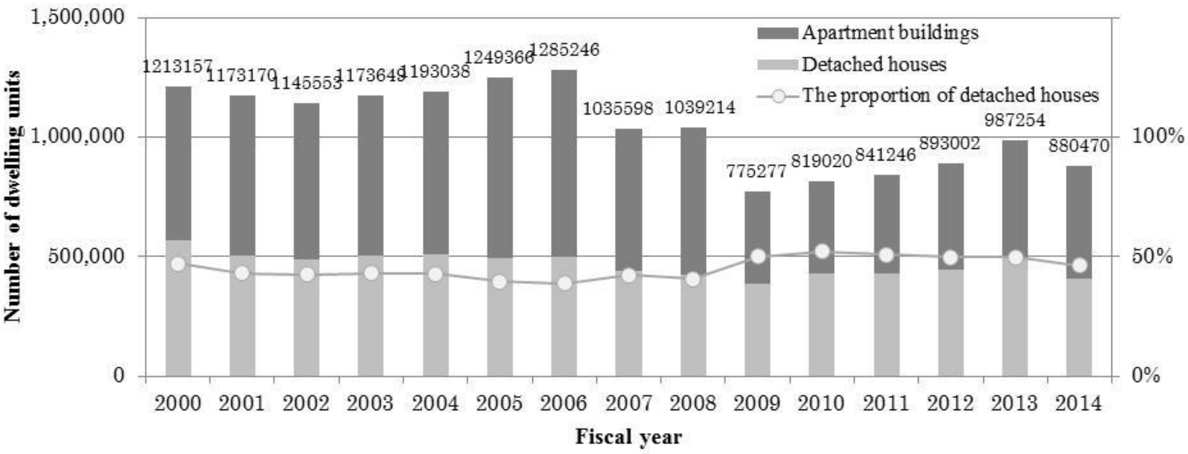

Figure 1: An annual number of newly built houses in Japan 2000-2014

There are various trial estimations[4] of the service life of houses. Figure 2 shows the data estimated by the Ministry of Land, Infrastructure, Transport and Tourism as an example of the service life of houses in Japan[3]. The average service life of houses in Japan is shorter than that in the US and the UK. This means new family builds new house and their children's generation don't succeed to stay nor doesn't another family stay at the house. The following reasons may be significant.

- Japanese people strongly prefer new houses to existing ones. (e.g. in 2008 fiscal year 13.5% of the housing transactions was for existing houses.)

- There is a tendency to treat that the value is lost for existing houses over a certain age in Japan

- Implementation of future renovation is not considered in the initial design concept of houses

- During the high economic growth period, people paid much attention to the quantity than the quality. The renovation of less performance houses needs much more cost.

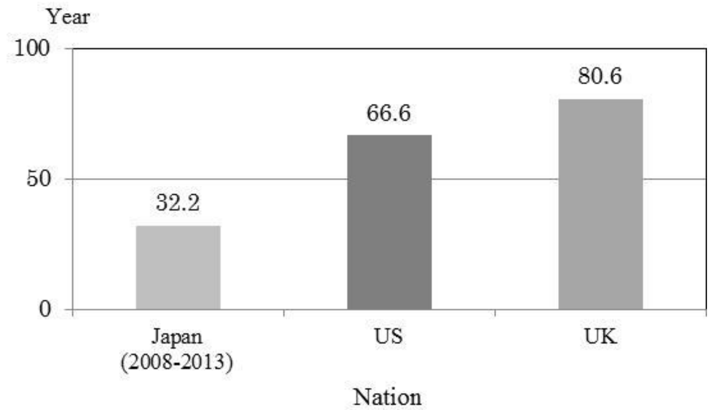

Figure 2: The average service life of houses

2.2 The need for the system for settlement of the housing disputes in Japan

The following three features are key differences between houses and other goods and services.

1. Houses are very expensive. For many people it is the most expensive purchase in their life. Usually they will buy their own house with the help of a long-term mortgage of 25 or 35 years. If the purchased house had the defects, the purchasers feel the great disappointment and would like to know how to handle.

2. Despite the largest purchase of their life, the homebuyer usually has less knowledge or information about the construction quality of the house.

3. Houses are built by combining a variety of materials and construction methods. Because technologies and terminology related to architecture are relatively complex, the consumers do not generally understand them. The purchaser is trying to verify the construction

quality, but because the construction work is carried out over a long period, and because access to some areas (such as sub-basements and roof spaces) is difficult it is not feasible for the consumer to check all of the components and processes. Additionally, there are a number of elements that cannot be tested in a non-destructive way. Verification that design specifications have been met in the actual building is very difficult.

In Japan, because the service life of houses is short, residential new construction opportunities are greater than the other countries. For the above reasons, to resolve disputes related to housing, a neutral expert is desirable.

Dispute resolution has traditionally meant a court trial. In general, court proceedings are slow and expensive. Litigation related to architecture has a strong tendency to take longer than the normal civil litigation. The reasons for prolonged proceedings are in part due to the time it takes time to verify the professional knowledge and to separate objective evidence from emotional conflict (such as the owner's feelings for their own house).

There are alternative dispute resolution ADR procedures that seek to solve conflict outside the court system. ADR is the dispute resolution process that experts such as lawyers encourage, where resolution is achieved by agreement between the parties by involved.

Conflict resolution in housing requires the participation of both lawyers (as legal experts) and technical experts such as architects – who provide knowledge of the technical aspects related to the building. ADR is a simple procedure and can provide a rapid resolution when compared to a trial. We can say that the advantage of the ADR is it allows for agreement between the parties without disclosing that disputes have occurred.

3. The background of Institutional establishment and legal basis

3.1 The background of Institutional establishment

The housing dispute settlement system in Japan is supported by "The Housing Quality Assurance Act HQAA" and "The Act for Secure Execution of Defects Warranty Liability under HQAA".

Prior to enactment of "The Housing Quality Assurance Act HQAA", housing defects have been considered under the provisions of the Civil Code[5)]. The provisions of the warranty for the building construction contracts are stipulated in the Civil Code Article 634 and 638. The article 638 defines the warranty period for new houses. The defined period is five years for buildings of light structure (e.g. wooden buildings), and ten years for building constructed of reinforced concrete or similar materials. The provisions of the warranty for the sale contracts are Civil Code Article 570 and 566.

Contracts with different warranty periods were also allowed by the freedom of contract principle. This act has since been defined as invalid as it could adversely affect a purchaser.

Around the end of the 20th century, many poorly-performing houses were sold. It became the social problem. As a result "The Housing Quality Assurance Act HQAA" was passed, calling for the establishment of a House Performance Indication System, Housing Dispute Resolution System, and Special Case for Defects Warranty Liability.

Several years later, the seismic building code scandal happened. It was discovered that the structural capacity of some multiple - dwelling complexes had been deliberately lowered. According to the ruling of HQAA, repair expenses should be demanded by the house owner and met by the vendor. But some house vendors went bankrupt before being able to meet these demands. As the result, many consumers could not receive compensation for housing defects, and some people were not only obliged to continue to pay the remaining mortgage, but also lost their houses in the multiple-dwelling. Following this social problem, a policy to secure the compensation was introduced.

3.2 "The Housing Quality Assurance Act HQAA" and assessed houses

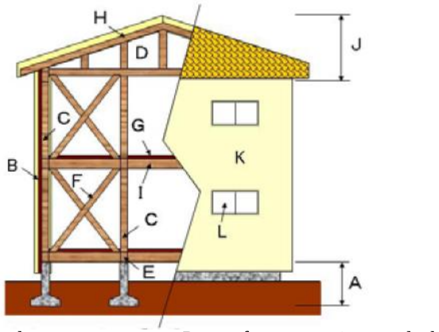
"The Housing Quality Assurance Act HQAA" was enforced in April 2000. The main details of this act are outlined below

1. 10-year warranties for principal structural parts and parts used to prevent rainwater leakage became mandatory in new housing sales and constructions contracts

2. Common rules for housing performance indications were established by the government

3. A housing dispute settlement system was introduced

The house vendors and contractors of new houses had to bear the warranty responsibility of 10 years for the elements necessary for structural resistance and the elements used to prevent rainwater leakage. The Act is limited to the important parts required to maintain structural rather than targeting all parts of the house. Figure 3 shows an image of the applicability of defect liability under the Act. The left and right figures[6)] show applicability for a detached house and co-housing, respectively.



Principal structure parts		Parts of prevent rainwater leak	
A	Foundations	J	Roofs
B	Walls	K	Exterior Walls
C	Columns	L	Openings

Case of an apartment house of reinforced concrete structure (wall type structure)

Figure 3: Part of the house that is the subject of the Act

The mandatory 10-year guarantee determined was accompanied by the concept of optional labelling. A new house which has been evaluated for performance is called an "Assessed House". Figure 4 shows the number of households receiving residential delivery of a construction housing performance evaluation report[7]. The number of assessed houses increased steadily from establishment of the evaluation system in 2000 until 2007. Since then a relatively constant 20% percent have received a construction house performance evaluation. Under the HQAA, disputes related to the contract should be solved by alternative dispute resolution (ADR) where possible. Approximately 20% of new houses apply the labelling, which has the benefit that both the house vendor and the purchaser are guaranteed the option of using ADR as a dispute settlement system.

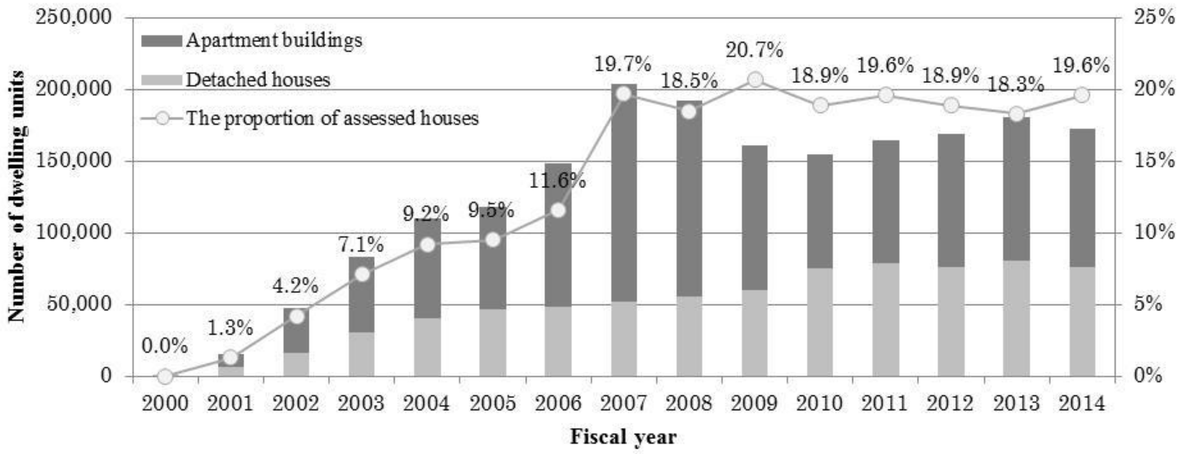

Figure 4: An annual number of newly built assessed houses in Japan 2000-2014

3.3 "The Act for Secure Execution of Defects Warranty Liability under HQAA" and insured houses

In April 2008, "The Act for Secure Execution of Defects Warranty Liability under HQAA" was enforced. A housing defect liability insurance scheme and an associated dispute resolution system were introduced. Eighteen months later, in October 2009, mandatory measures were enacted to ensure that new house suppliers have adequate financial resources. The Act demands that suppliers either participate in deposit schemes or purchase defect warranty insurance. New houses are covered by housing defect liability insurance called an “Insured house”.

Figure 5 indicates the annual number of dwelling units and the percentage of insured houses[7]. The number of insured houses has increased sequentially from 2008 to ensure measures are mandatory of resources. By 2010 (the third year after the introduction of the system) approximately half of new houses were covered by housing defect liability insurance.

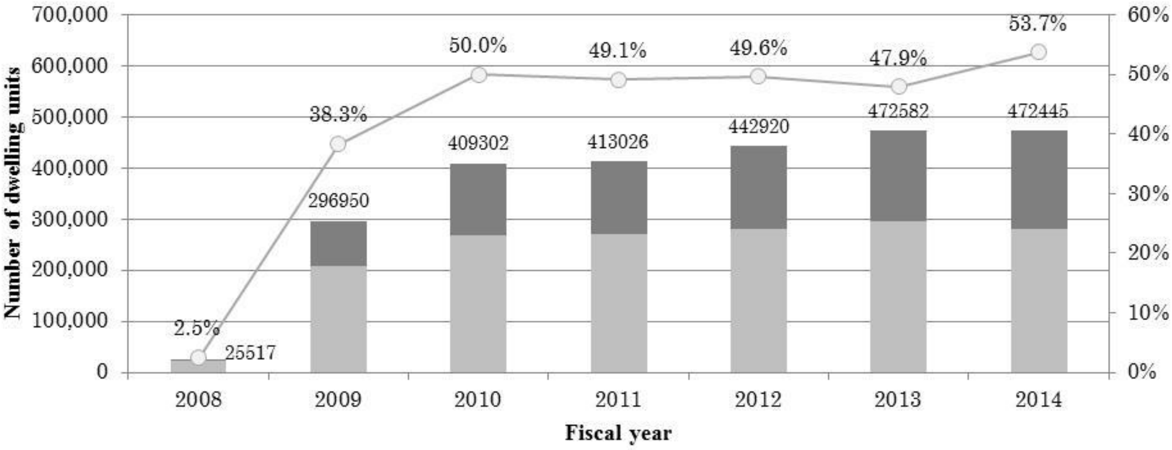

Figure 5: An annual number of newly built insured houses in Japan 2008-2014

The Ministry of Land, Infrastructure, Transport and Tourism reported the share of types of financial resources that housing suppliers have selected to use. Figure 6 shows the results[3]. More than 99% of housing companies have chosen insurance. The deposit schemes are used by less than 1% of housing companies. Taken together with the fact that the ratio in the number of units is roughly 50:50, the deposit scheme means that there is a strong tendency for many leading companies use deposit scheme.

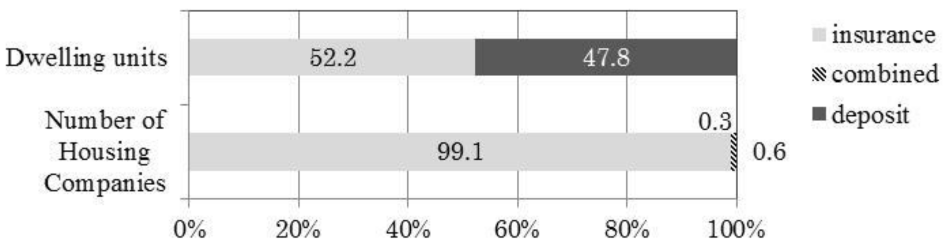

Figure 6: Resources secure method for repair

The new ADR scheme is also applied to "insured houses". Ignoring overlaps, the proportion of insured houses is 2.5 times greater than that of assessed houses, and housing defect warranty insurance will cover more than 99% of the companies. So, one of the notable point of this act is the expansion of the ADR scheme has included many small and medium-sized enterprises that have a relatively weak financial base.

3.4 The system for settlement of the housing disputes in Japan

The dispute resolution scheme that is applied by the two laws is the same. The overall flow for the system for settlement of the housing disputes in Japan[8] is shown in Figure 7. This scheme is private type ADR which does not receive the financial support from the government.

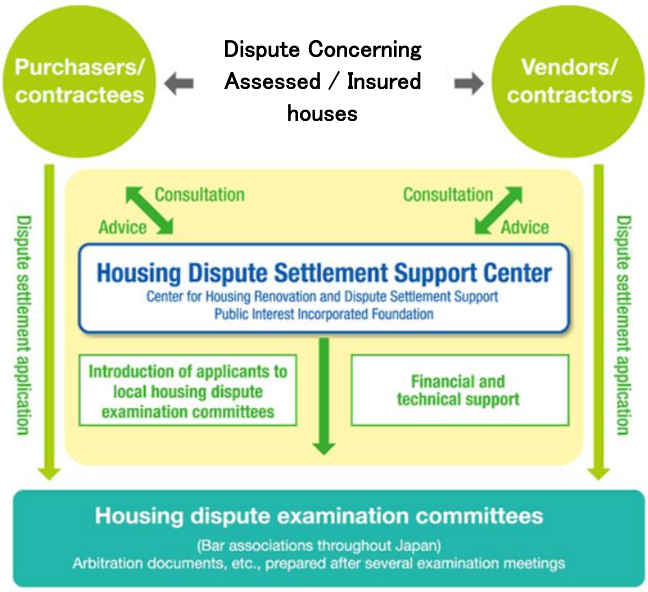

Figure 7: Dispute settlement flowchart

Based on the HQAA, the 52 bar associations in Japan are designated as housing dispute settlement bodies. Housing dispute settlement (for assessed houses and insured houses), disputes concerning sales and constructions contracts are available when they occurred. This housing dispute settlement treats the very broad issue, such as agreement, payment and delivery, post-purchase incidents and so on.

If the dispute about the contract between the vendors-purchasers and the contractees-contractors relating to assessed or insured houses has occurred, the parties will be able to apply for the dispute settlement to the housing dispute settlement bodies. On acceptance of the application, housing dispute settlement begins.

Lawyers and registered architects who are neutral fair third parties participate in housing dispute settlement as committee members. The committee promotes solution by mutual agreement. In the process of dispute resolution, a hearing will take place or the parties' documents will be examined. If necessary a site survey and appraisal will be performed.

The housing dispute settlement support center (the support center) is the only institution has been specified in Japan by the provisions of the Act. The support center will introduce a housing dispute settlement system to the questioners when the support center has received a consultation on assessed and insured houses. Also the support center introduces a nearby Bar Association to the parties as required.

The support center provides a number of services including the subsidy required for dispute settlement cost, advice based on similar previous cases and judgements, provision of building technology information.

4. Related services that contribute to the housing dispute settlement

This chapter introduces the two services to support the housing dispute settlement.

4.1 Telephone consultation

A telephone consultation service is provided for consumers who suffer from anxiety or trouble related to the acquisition or renovation of houses. It covers both technical and legal issues, Telephone counsellors are registered architects. Answers to legal issues are provided by a resident lawyer. Telephone consultation is available on weekdays except for the year-end and New Year holidays. Consultation will have been carried out in a manner to reduce the burden of telephone charges. Figure 8 shows the flow of telephone consultation[8].

Figure 8: Housing consultation flowchart of telephone consultation

4.2 Expert advice

Services of the face-to-face consultation in cooperation with 52 bar associations across Japan are provided to the people who would like to further help with problems related to the assessed houses, insured houses or housing renovation. This service is free; lawyers and registered architects have attended, and give advice from both the legal and technical sides. This consultation is called expert advice. In the face-to-face consultation, participants can bring the relevant documents such as the contracts, the drawings and the photographs, and advice is provided on the basis of those materials. Figure 9 shows the flow of expert advice[8)].

Figure 9: Expert advice flowchart

5. Conclusions

Part 1 was an overview of the system of private type of housing dispute settlement in Japan. We described the condition of Japanese houses as a background to institutional establishment and related services that contribute to the housing dispute resolution. We illustrate the application performance of the system in Part 2.

Housing Dispute Settlement System in Japan; Part 2 - The results and present conditions of the housing dispute resolution

Hiroshi Ito and Masaaki Suga

Center for Housing Renovation and Dispute Settlement Support
Email: itou@chord.or.jp

Abstract

In this report, we summarize the Japanese system for settlement of housing disputes.

We will detail the background of the legislation and the establishment of the system, along with the current state of the system and operational results.

We posted two related papers to WBC16. In this second paper, we discuss the operational results and present conditions of the system application.

Keywords: Housing defect, Housing dispute settlement, ADR, Legal & Technical advice, Consumer

1. Introduction

This report introduces the Japanese system for settlement of housing disputes.

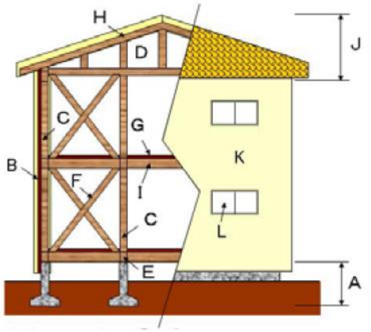
We previously mentioned Japan's housing situation, the need for the system for settlement of the housing disputes and the background of the housing dispute settlement to the legislation in part 1.

In this paper we show the results of an analysis of data that collected in the process of providing the housing dispute settlement service, the telephone consultation service and expert advice.

2. Assessed houses and Insured houses can use the housing dispute settlement

2.1 Assessed houses

“The Housing Quality Assurance Act HQAA” was enforced in April 2000. Under the act vendors and constructors of new houses have to bear responsibility for the elements necessary for structural resistance and the elements used to prevent rainwater leakage via a 10-year warranty. Figure 1 shows an image of the applicability of defect liability under the Act. The left and right figures show applicability for a detached house and an apartment house, respectively.



Principal structure parts		Parts of prevent rainwater leak	
A	Foundations	J	Roofs
B	Walls	K	Exterior Walls
C	Columns	L	Openings
D	Roof trusses		
E	Sills		
F	Diagonal Members		
G	Floor Slabs		
H	Roof Slabs		
I	Horizontal framing Members		

Case of a detached house of wooden structure (post & beam traditional structure)

B	Foundation Piles	G	Exterior Walls
C	Walls	H	Openings
D	Floor Slabs	I	Drainage Pipes
E	Roof Slabs		

Case of an apartment house of reinforced concrete structure (wall type structure)

Figure 1: Part of the house that is the subject of the Act

New houses utilising Housing Performance Indication System are called an “Assessed House”. Figure 2 shows the number of the houses receiving the evaluation reports. The number of assessed houses increased steadily from the establishment of the evaluation system in 2000 to 2007. After that a relatively constant 20% percent have received the evaluation reports. The HQAA enables both vendor and the purchaser of an “assessed house” to utilise newly introduced ADR as a dispute settlement system.

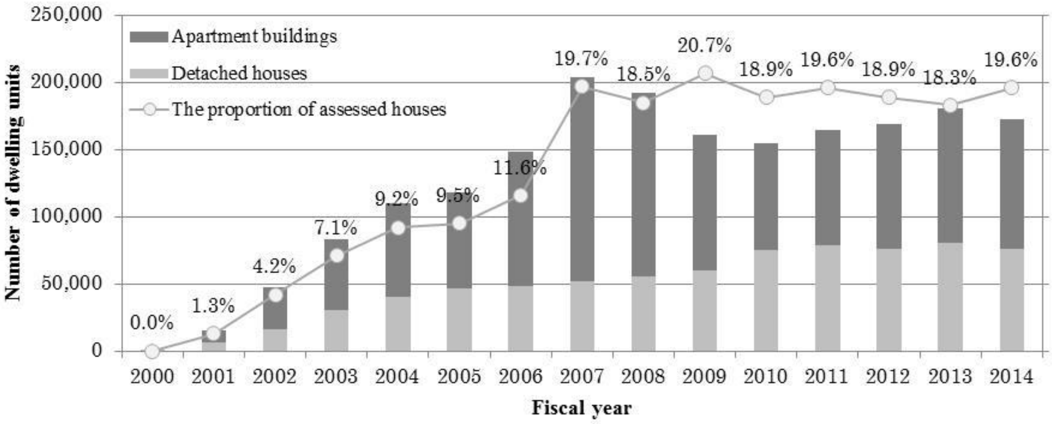

Figure 2: An annual number of newly built assessed houses in Japan 2000-2014

2.2 Insured houses

New houses are covered by housing defect liability insurance called an "Insured house".

Figure 3 indicates an annual number of insured houses and the percentage against newly built houses. The number of insured houses has increased sequentially from 2008 to ensure measures are mandatory of resources. By 2010 (the third year after the introduction of the system) approximately half of new houses were covered by housing defect liability insurance.

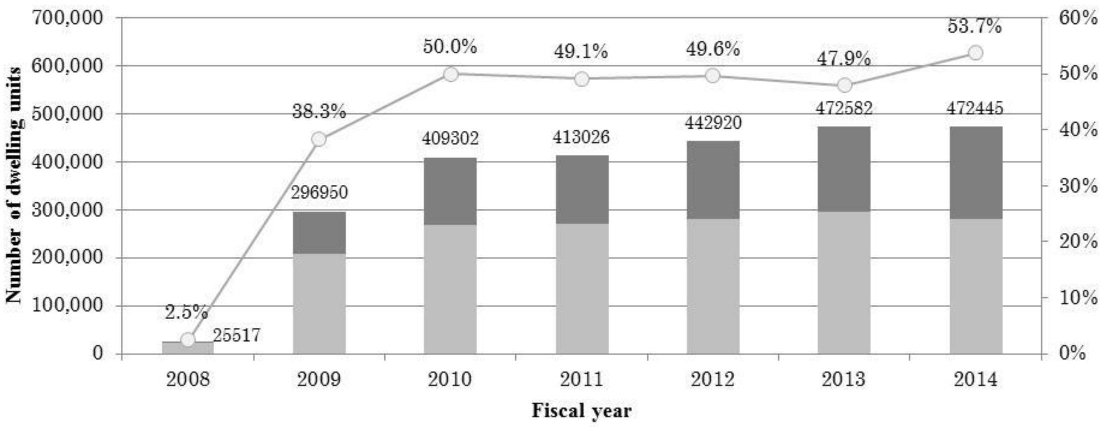

Figure 3: An annual number of newly built insured houses in Japan 2008-2014

3. The application results of the system for settlement of the housing disputes in Japan

The overall flow for the system for settlement of the housing disputes in Japan is shown in Figure 4.

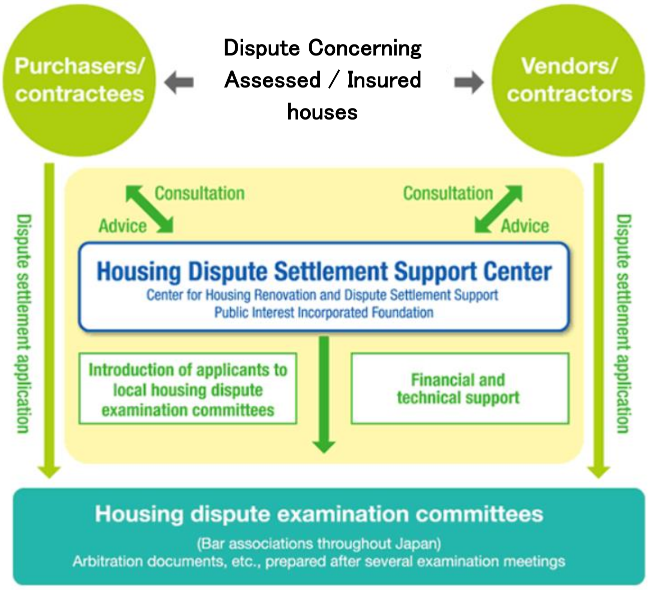

Figure 4: Dispute settlement flowchart

Figure 5 shows the dispute settlement filings after the system started. The first dispute application for an assessed house was processed the fiscal 2001, and number of applications has then gradually increased. Between 2005 and 2009, there were 20-30 requests per year.

"The Act for Secure Execution of Defects Warranty Liability under HQAA" was enacted in 2008, and as a result insured houses became subject to the same dispute settlement scheme as assessed houses. This has led to a significant increase in dispute settlement filings from fiscal 2010. In future, continuous increase in the number of applications predominantly from insured houses will be expected.

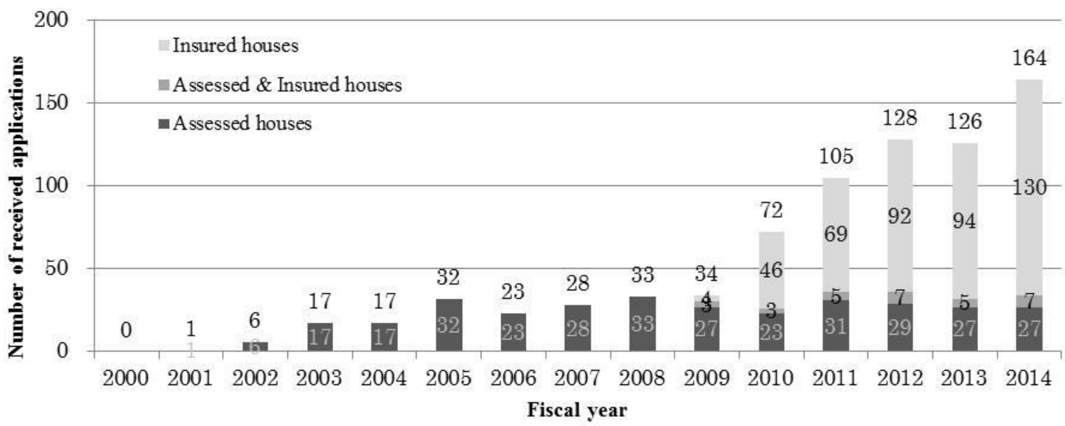

Figure 5: Dispute settlement applications received 2000-2014

Figure 6 shows the number of the dispute settlement applications after the process of the expert advice and the proportion against all dispute settlement applications. The proportion indicates an increasing trend.

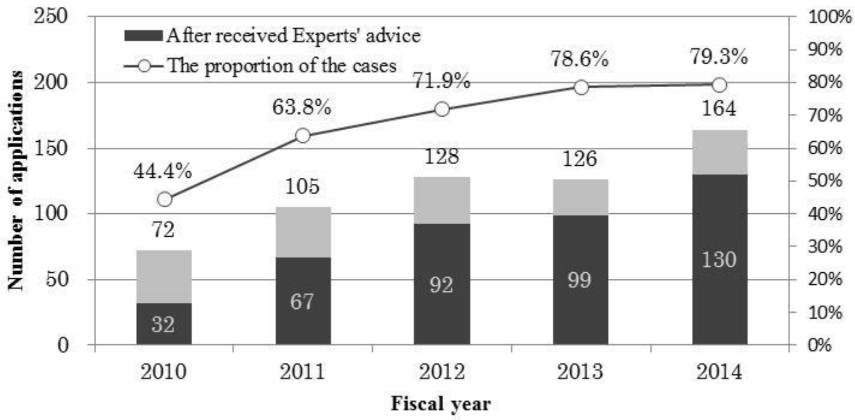

Figure 6: Number of the dispute settlement applications after expert advice 2010-2014

Figure 7 shows the results of the dispute settlement process for a total of 684 cases processed by 2014. 53.5% (366 cases) have been resolved by mutual agreement.

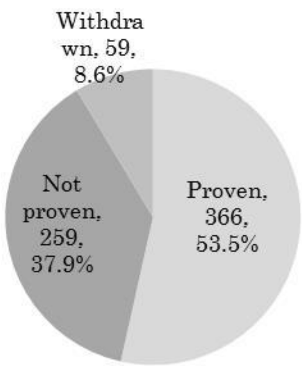

Figure 7: Results of dispute settlement (n=684)

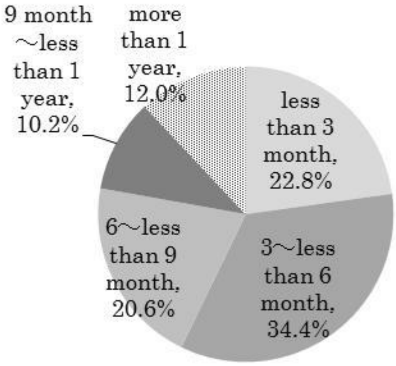
Figure 8 shows a length of the conflict resolution process. The greatest proportion of cases took between three and six months, although the average case took 6.6 months (close to our target 6 month timescale). The number of consultations for each case is shown in figure 9. Around two-thirds of cases (66.5 percent) required less than 5 times consultations. The average was 4.7 times.



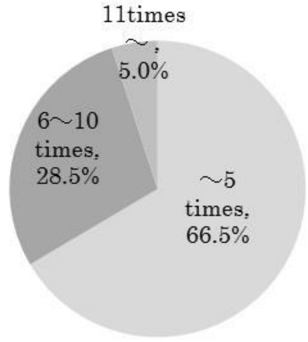


Figure 8: Trial period (n=684)   *Figure 9: Trial number of times (n=684)*

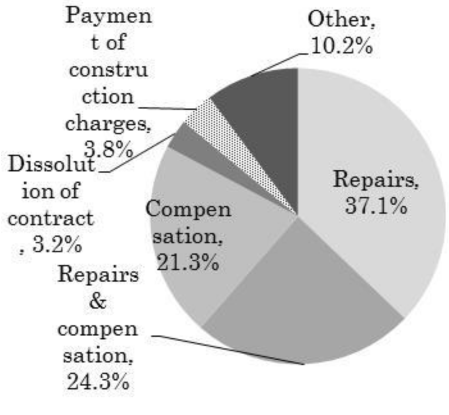
Figure 10 shows the desired resolution when the application filed. The Resolution in the resolved cases (n=366) are shown in Figure 11.

The most common outcome desired was “repair”, followed by “repair plus compensation” and “compensation only”. The most common outcome was “repair” followed by “compensation” and “repair plus compensation”



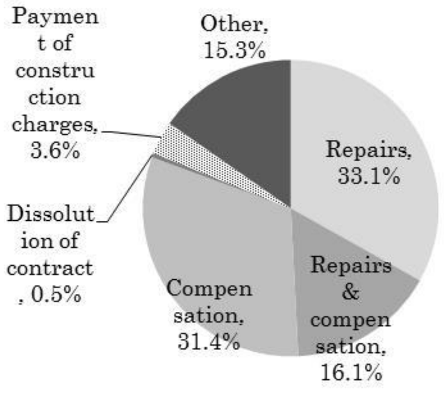


Figure 10: Initial hope (n=684)   *Figure 11: Agreed solution (n=366)*

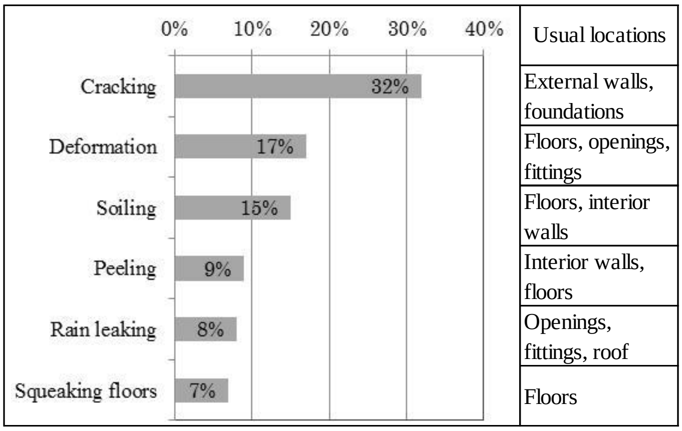
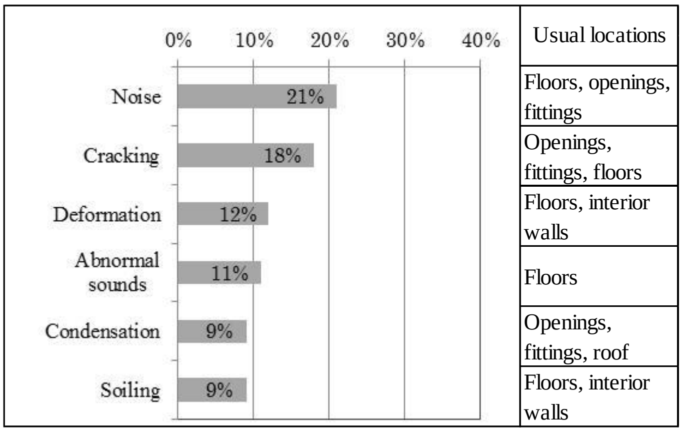
The issues in dispute are listed in Table 1 & 2. The most common problem in detached houses is “Cracking” whilst “Noise” issues are most common in apartments.

Table 1: The main trouble events that became issue of dispute settlement on detached houses n=406 (multiple counts)



problem counted multiple times (n=406)

Table 2: The main trouble events that became issue of dispute settlement on apartment building n=151 (multiple counts)



problem counted multiple times (n=151)

4. The application results of the related services that contribute to the housing dispute settlement

This chapter introduces the two services that support housing dispute settlement.

4.1 Telephone consultation

The telephone consultation service, covering both technical problems and legal issues, is provided for consumers who suffer from anxiety or trouble related to the acquisition or renovation of housing. Figure 12 shows the flow of telephone consultation.

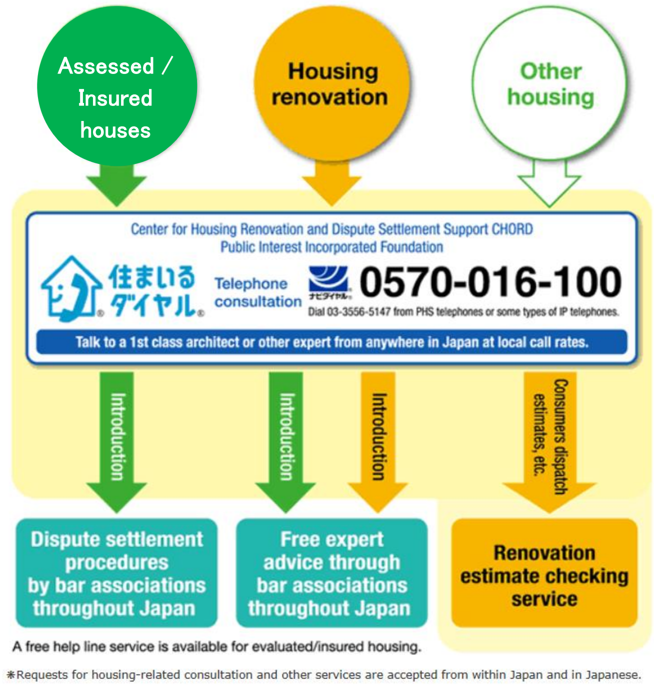


Figure 12: Housing consultation flowchart of telephone consultation

Figure 13 shows the corresponding record of telephone consultation. In the first year (fiscal year 2000) of the service, about 4000 calls were handled. The number of consultations increased after the enforcement of "The Act for Secure Execution of Defects Warranty Liability under HQAA" in 2008 and exceeded 26,000 in the fiscal 2014. In recent years the support center has been receiving telephone consultations for over 100 new cases per day. Approximately 60% of consultations relate to new houses, with the remaining 40% being consultation about renovation.

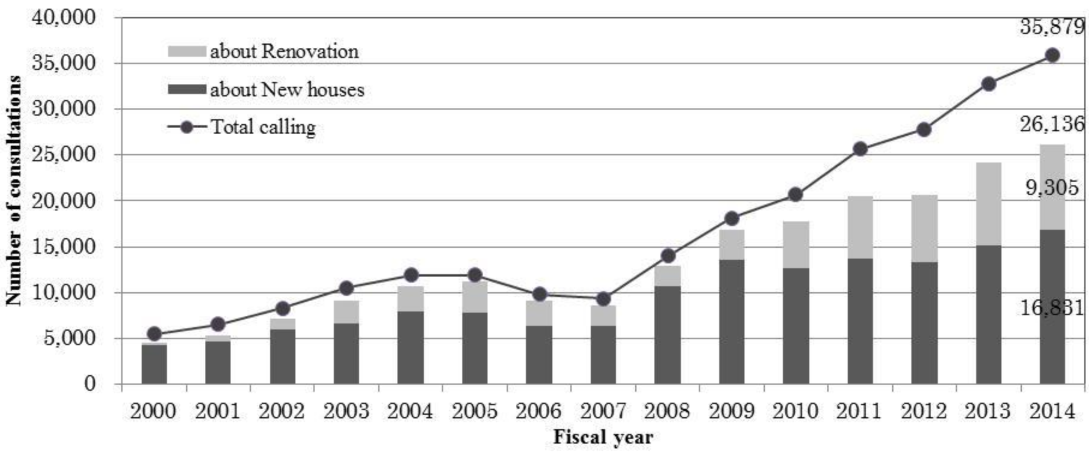

Figure 13: An annual number of telephone consultations 2000-2014

Figure 14 shows a breakdown of the consultations about housing issues for 2014. The pie chart on the left shows the reasons for the consultation across 16,831 incidents. The pie chart on the right shows the percentages for assessed and insured houses. The group on the right shows a 10% greater proportion of consultations relating to troubles. This trend was similar in the fiscal 2012 and 2013.

Figure 14: The proportion of telephone consultations about trouble on 2014

4.2 Expert advice

Face-to-face consultation services are provided in cooperation with 52 bar associations across Japan. Figure 15 shows the flow of expert advice.

Figure 15: Experts advice flowchart

Figure 16 shows the number of the expert advice consultations since they were introduced in April, 2010. The number of consultations has increased every year to more than 1,800 in the fiscal 2014. The expert advices concerning the renovation accounted for 50% of the cases.

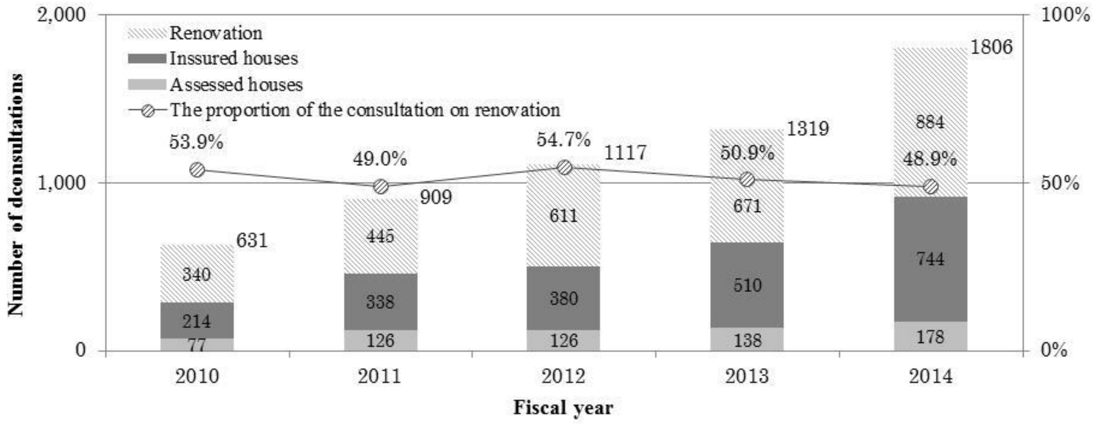

Figure 16: An annual number of expert advice 2010-2014

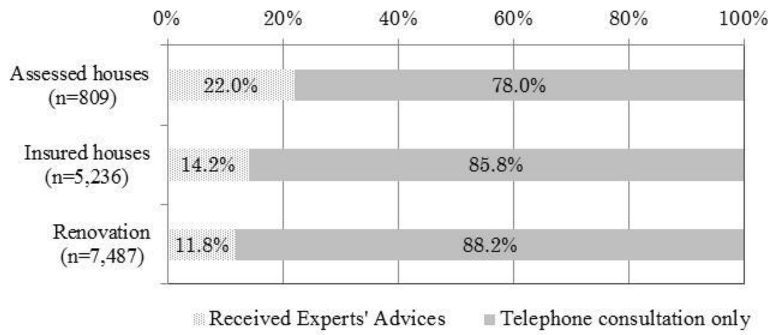
Figure 17 indicates the number and the percentage of people using expert advice that had previously received a telephone consultation. Of the 178 cases relating to assessed housing, just 22% had previously had a telephone consultation; even fewer of the 744 insured housing cases (just 14.2%) used telephone consultancy first. Cases to proceed to expert advice through the telephone consultation are a minority. There is a possibility that telephone consultations are to contribute to the prevention of housing dispute.



Received Experts' Advices	Telephone consultation only
178	631
744	4,492
884	6,603

Figure 17: The number and proportion of the expert advices after telephone consultations

Figure 18 shows the reason for the use of the expert advice. The total is greater than 100 percent, as multiple reasons can be given. Nearly 90% of users chose the reason that lawyers and architects have attended, giving the user expert advice from both legal and technical perspectives.

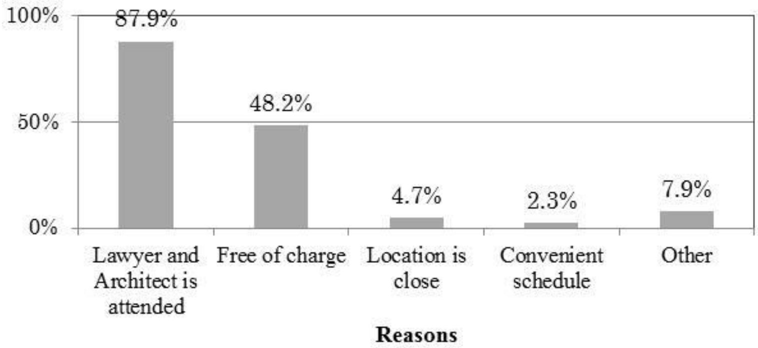


Figure 18: Why the expert advices used (multiple choices)

Figure 19 shows how satisfied users are with expert advice consultations. User satisfaction is considered high based on the fact that 90% were "Highly satisfied" or "Satisfied" with the service.

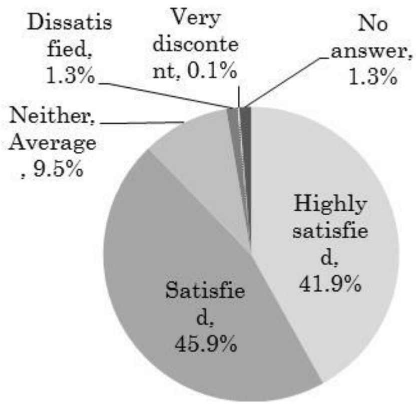

Figure 19: User satisfaction of expert advice (n=1345)

In the case of consultation on assessed or insured houses, the support center will introduce a housing dispute settlement of the Bar Associations in response to the consultation.

5. Conclusions

Part 2 has shown the results of the housing dispute settlement, the face-to-face expert consultation and the telephone consultation as well as the cause of the housing dispute and the satisfaction of the users. The users of all three services have been increasing year by year. This means that the Center For Housing Renovation and Dispute Settlement Support CHORD has accumulated the data of those three services. Under the condition that the secret of these data should be kept, the accumulated huge data should be analysed and utilised for the housing consumers and suppliers to prevent housing disputes and to do the prompt and effective dispute settlements.

Stakeholder involvement and satisfaction

Housing association objectives and the results of indices in the Netherlands

Jan Veuger

NoorderRuimte, Centre of Research and Innovation for Build Environment,
Hanze University of Applied Sciences Groningen, Netherlands
Email: j.veuger@corporaterem.nl

Abstract

Housing associations make too little a contribution to Society, the government has to step in too frequently because of maladministration, and the associations' executives are often unaware of the far-reaching impact of their decisions. These are the conclusions of new academic research conducted by Jan Veuger of Rotterdam School of Management, Erasmus University (RSM). In his dissertation, he asserts that in numerous cases there is no correlation between social and financial objectives. The Dutch House of Representatives debated the results of the report 'Ver van huis' from the Parliamentary Committee of Inquiry on Housing Associations in early December 2014. After extensive exploration of the literature and PhD studies on the period from 2005-2009, the research design inspired based on the grounded theory, which has a certain bias as a result of the extensive literature study. In the line of thinking of the grounded theory, interviews with directors contacted more or less uninhibited according to a narrative method. Afterwards these interviews, independent of the researcher, thematic and labeled by a single Delphi method have been submitted to an expert group which created a storyline. The results of this Delphi method were submitted to a peer group of directors. The conclusions were presented in a survey to 60 selected directors and the subsequent conclusions. There has thus been more than a triangulation of research than just interviews, Delphi method and survey. Hypotheses are thereby omitted because of the difficulty of fitting in within the chosen research design inspired by grounded theory. At his request Stef Blok, Minister for Housing and Kingdom Relations, has received the thesis Material Immaterial (Veuger 2014) on December 4, 2014. On December 11, 2014, the Minister decided to change its proposed policy through the establishment of an inspection model in which the financial and social objectives of the corporations are tested and assured, with the Minister as the final responsible. The parliament has unanimously agreed.

Keywords Control – housing associations – social values – board – MSCI IPD index

1. Introduction: in the eye of the hurricane

Before starting the study of control and appreciation of housing associations there was in my opinion a real chance that housing corporations might actually end up in a danger zone of legitimacy and the right to exist. The question I then asked about the contradictions there are in the social values of housing associations that affect the way they are governed, is still relevant. The reputation and trust in housing corporations has also decreased dramatically in recent years. The question is what is really going on at housing associations about control and appreciation.

An extensive study of literature and (PhD) studies on the period from 2005 until 2009, with a present potential of 720 professional magazines in the field of housing and real estate, 149 articles were found to be relevant with the inclusion criteria: values, control and corporations. Therefore are these 149 articles all included in the bibliography. From these articles emerges a picture about values and control of housing associations which are mostly financially oriented and much less socially. Reason to start a PhD research to get a grip on societal values and control of housing associations. After the extensive exploration of the literature and (PhD) studies on the period from 2005 until 2009, the research design was inspired on the basis of the grounded theory, which has a certain bias due to the extensive literature study. Following the line of thinking of the grounded theory, interviews with directors, have started, more or less unprejudiced, according to a narrative method. Afterwards these interviews were, independent of the investigator, thematically labelled by a single Delphi method - appropriate in the line of grounded theory - and submitted to an expert group creating a narrative. The results of this simple Delphi method have been submitted to a peer group of directors. Afterwards these conclusions were presented in a survey to 60 selected directors to raise the subsequent conclusions. So there has been more than a triangulation of research by interviews, Delphi method and survey.

After this introduction, this article is based upon the methodology of the survey, the results of research on control of housing associations in the Netherlands, the European context of housing associations and final justification of the IPD Netherlands Housing Property Index over the policy of housing associations about a certain period of time in terms of returns.

2. Methodology

The *grounded theory* is a method developed in the 1960s by Glaser and Strauss (1967). The emphasis of the method is to generate a theory based on data. Because not expressly in advance is to determine what the missing operating and monitoring questions are, it is of interest to collect data to a saturation point because it may be assumed that there is no more new information to generate on this topic. The grounded theory is flexible and is able to highlight questions that have not been previously asked. Fed by the pragmatic legal theories, ethnographic research – bringing information about dividing lines between different communities – and explicitation of qualitative methods, Glaser and Strauss intended to codify procedures. They can be summarized by reasoning, to handle more deliberate on the one hand and, on the other hand, they become to theory. Glaser and Strauss's approach indicates that the quality of a theory can be evaluated by the process by which a theory is constructed.

Methodical over a period of five years of literature, ten years of stakeholders, instruments and behaviour and a hundred years of housing corporation history, the developments in the field of value thinking and the governance of housing corporations have been studied. This qualitative study with a positivistic approach of values and governance of housing corporations has answered the research question What social values underlie social housing and are there contradictions that affect the control of a social housing corporation? The grounded theory is the research method chosen as a line of thinking, because that method emphasises the generating of theory-based data. Because it is flexible, it enables us to highlight questions that have not been asked before. These questions have been evaluated by the process with which the theory of this study has been constructed.

The Process of this Research

This research inspired by the grounded theory follows an inductive method for development of that theory. This process of collection of data about thinking in terms of values and control begins with the open encoding – a combination of the concepts of values, control and corporations – data in the professional literature in the field of opinion and scientific research over the period of 2005-2009. The found fragments are reduced to a number of concepts such as those in the relevant chapters are examined. By the interaction of comparisons of terms a smaller number of concepts is created to which different dimensions can be awarded. This is leading to a certain saturation process. By the relating of concepts arises a theory that flows into a story line. This storyline is surrounded by tables and overviews for a rich presentation of evidence and a clear statement of arguments.

The final result of this research is a description of missing operating and monitoring questions, the collected and saturated core concepts that explain certain events. By this methodology an understanding of patterns and processes is revealed. 'This makes clear how a group of people, through their social interactions, their reality and defines acts' (VOC 2010:17). Not the theory is leading, but the practice on which research is being done. The choice for this theory formative research is has been made because the research question requires insight in missing operating and monitoring questions. The answer need not to be found in the existing practice or theory, but lies in not yet asked questions that can offer a solution in the area like Einstein this describes as 'the actual problems cannot be solved at the same level of thinking, in which we were when we created them'. The power of the grounded theory is that it is detailed in the descriptions of the method of data analysis and gives a possibility for the research draft anchoring and accountability. This allows that difficulty of validation and generalization can be parried. Later on additional literature research and findings in the study are faced with the insights from the theory. By this method of constant reflection additional insights in the analyses are created; the dialogue between theory and practice and enhances the consistency of the description of this research to understand. The process of this research is from step to step, where each step validity is ensured. The different phases, with underlying steps of this study are included in the following figure, inspired by Pandit (1996). The phases and steps are related to the chapters of this study.

3. Control of Housing Corporations in the Netherlands

Why this qualitative research into control of housing associations? To understand and to discover patterns about the how and why of the operation of housing associations in society as they do now. This qualitative research is about the search for ideas, backgrounds, motives, resistors and rationale and is therefore suitable for the following central question to answer: are there contradictions in the social values that underpin housing associations that have an impact on the way they are governed? Partial questions here are: (1) how can be arranged that the social objective behind the values becomes transparent?, (2) what is that social enterprise Housing Corporation, what is its role in society and what is social real estate?, (3) how can values and orientation of corporations on the basis of the criterion be of social relevance?, (4) how does the executive now operate in practice, does he usefully apply operating models and the theories about Corporate Real Estate Management (CREM), which are based on the commercial sector?, (5) how does innovative control of housing corporations look like? and (6) how to get an insight in operating questions about social real estate?

Methodical literature over a period of five to ten years, instruments and stakeholders behavior and hundred-year history of the housing corporations, the developments in the field of values in thinking and driving housing corporations are examined. This qualitative research into values and control of housing associations, the research question answered. The grounded theory is chosen as a line of thinking for the qualitative research method because the emphasis is on generating the data based on theory. By being flexible, being able to highlight questions that have not been previously asked. These questions are evaluated by the process by which the theory of this study is constructed.

In this review values are examined in relation to social real estate. The social real estate as an object is made up of material value. This material value is necessary for the commercial power of the Corporation, with which they control public real estate and the organic value. The social real estate is a prerequisite for the operation of the Corporation, the social value. Particularly in the relation of public real estate and the Corporation is that they can exist separately, but the Corporation is not able to operate without social real estate. The social real estate retains its values without the Corporation, but not the other way around. The combination in its entirety creates an intellectual value. Corporations are focused on creating social value by deliberately allocating resources for social objectives and want to preserve, restore and refresh this value. Social integration and planning of the sector are important in determining which behavior is preferred. The Corporation executive appears however to stick to its own accumulated power and can hardly be influenced. Looking inside the Organization, it is noticeable that the investment behavior within the Corporation is generally in line with the personal conduct of the executive. Performance indicators as power and money, in which the executives are neglecting the current financial crisis, are still leading.

It is also not about a new organizational infrastructure, but above all improving the effectiveness, efficiency and financial position fueled by the pneuma – in the spirit of the work – related to the statement of the Corporation. The interpretation of this and the raison d' être of the Corporation can be found in a more offensive cooperation, new forms of mutual solidarity and thriving on the added values of the Corporation. In improving the social objectives of corporations three partly domains are to be distinguished: (1) housing the primary target group, (2) investing in the living and housing environment and (3) contributing to the socio-economic developments of districts. In doing so, its financial position, efficiency, effectiveness, transparency and planning of value-drivers are of importance. The Corporation also has three balanced values: (1) the fixed value (continuity), (2) the direction value (initiator) and (3) the profitability value (the mutual influence of neighborhood quality and real estate value translated into social and financial value). In the task demarcation are thus the effectiveness and efficiency of importance. It comes to the maximization of the financial value, but on maintaining a minimum acceptable ability. A more conscious control on social returns is a prerequisite for effective and efficient work. The effectiveness of housing corporations can mainly be considered to be a responsibility of the State and the municipalities.

In practice the Board is not controlling in coherence between financial and social returns and trust. CREM as theory can play a role in conjunction of values. In contrast to criticism of corporations, it is professionalizing, but the question is whether they are sufficiently keeping the focus on the sustainability of professionalization. Otherwise chaos is organized. Why worrying about the instrumentation for comparisons and why is it not possible to have a quick fix arranged by the Corporation directors among themselves? The answer to this lies in three reasons: (1) the quality and reliability of the information flows is not on the desired level, (2) the Government is not steering and leaves it to the perfect free market operation and (3) the discipline of behavior of the Corporation which leaves much to be desired. Striking is that an explicit evaluation of the destination goal, related to previous objectives, is rarely measured. Could be assumed that this is not about rational led settings but to a controlled chaos. By Corporate Real Estate Management (CREM) the real estate portfolio can be in line with the needs of the core activity of the Corporation. The aim of this key action is not new. This creates an optimization of the added values of the result. A values-based real estate strategy not only enables a competitive Corporation, but also with a moral strategy.

The multidisciplinary nature of public real estate management is not a bottleneck as far as clear definitions and observations are available. If hard and soft skills are not related to each other they build a bottleneck in the total control of a corporation and its reporting on them. If a task and the measurement of it not defined and organized, controlling is of no use and correcting is not possible. The dimension time affects value concepts from a historical context. Changes of value definitions affect the rating and thinking in those concepts. In addition, rating is depending on the one that defines quality of life and how it should be appreciated. Real estate is a social challenge with varying meanings for people involved. The corporation is a method of financing and value in the sense of usefulness. The orientation on change has affected the innovation and agility of the Corporation and on different values. Orientation to change should be seen as proof that the Corporation is able to achieve real renewal of the built up achievements, to consolidate and enhance these. If she is able to do this, it will lead to a richer Corporation where everyone can support with new developments and ideas. The future leadership of a corporation in the Corporation world is not determined by the possession of assets, but how it can focus these funds on a particular purpose. But what would it bring us if the monopoly position of the Corporation sector is halted? In ethics, it is a question of values and value system within an enterprise. Rank, position and power are important criteria and generally more important than money. Money is the medium to rank, position and power. The financial and thus the real estate market, is a market that exaggerates by irrational behaviour. Fear of 'eat or be eaten' provides the mechanism of people. Financial and real estate markets are always so unstable and should always be regulated. The Corporation must above all have a serving and no prevailing role. Regulation is an attempt to bring together different images of reality. Anchor points for this are: private capital, manage transactions and regulation of major players, in which the State should create the counterbalance.

Part of the conclusions of this research are:

1. Improving the social objectives of the governance of corporations must be reflected in three domains: (1) housing as the primary target group, (2) investing in the living and housing environment and (3) contributing to the socio-economic developments of districts. Financial position, effectiveness and efficiency are important.

2. Existing legislation is in itself not blocking any task of the Corporation. The specific characteristic of the public real estate covers: (a) a building related to common social activity and (b) providing and facilitating stakeholders from a recognized societal interest.

3. Corporations are focused on creating social values by deliberately allocating resources for social objectives and want to preserve, restore and refresh these values. Social integration and planning of the sector are important whereas the behaviour of the executive is of importance.

4. The Executive Committee will control in practice with operating models, but does this not in coherence between financial and social returns, social confidence, effectiveness and efficiency. CREM as theory can bring a cohesion in social and financial values.

5. Stories and performance are not connected to each other by the executive. A possible solution for real innovation to the fourth age of housing corporations, is planning the cohesion of societal values that leads to its licence of existence to operate in the future.

6. The multidisciplinary nature of public real estate management is not a bottleneck if definitions and observation are clear. Not related to each other financial and non-financial assessment criteria create a bottleneck in the total control of a corporation and her reporting on them.

The summary conclusion as answer to the central question: 'are there contradictions in the social values that underpin housing associations that have an impact on the way they are governed?' is: *Yes. Executives who think at the highest level about how they should deal with values, ensure they control on their own, know what the consequences of their decisions are and take their responsibility.*

The research question has led to the conclusions and formed the basis for further research in the form of three follow-up propositions. These propositions deserve attention for further research on governance of corporations: the housing cooperative as a crowbar, the possible integration of Corporate Real Estate Management in between a Corporation and the Societal Autism of Corporation directors. The follow-up investigations are shown in the three propositions (a) a cooperative form – embodied by the Seven Cooperative Principles in 1844 – caused a bundle of values in socio-economic developments, (b) a non-monopolistic arrangement increases the future value of a corporation and (c) as long as social autism of Corporation directors continues, this blocks a change of Control. The Community would be leading about the objective of public housing if the inner striving for desire and power is controlled. The true value of a corporation is not organised by an executive in a controlled chaos on a sliding scale, but determined in the context of societal values that public housing can bring further. Substance is therefore immaterial: material immaterial. This science, built on facts, is like a house built of stones. And not an accumulation of facts as a pile of stones in the shape of a House.

The research is limited to the Netherlands in view of the complexity and topicality of the corporations in the Netherlands. But what makes the Dutch housing corporations now so unique in Europe? The next section places the Dutch Corporation also in the European perspective.

4. European context

Dutch politics has a general preference for a broad definition of the target group from the vision of the preventing of segregation and providing equal opportunities in the housing market, in comparison with a narrower definition in countries like Germany, Italy, Spain and Austria. Hieminga (2006) also distinguishes the social activities with support facilities – and in line with the service of general economic interest (sgei) definition – if (1) construction, rental, maintenance, renovation and possibly sales (whether or not under conditions) of rental properties in the regulated rent segment, namely the rental properties for the primary target group is clearly defined in terms of income limits, (2) the activities in the sense of promoting the quality of life and living quality as far as relating to regulated home ownership, (3) construction, rental and maintenance of social property meant for use by a social task, such as community schools, welfare buildings and such. Looking at the qualitative housing shortage and the influence of the tenants Gruis and Zijlstra (2006) conclude by means of a theoretical analysis that a client controlled stock has a very limited contribution to solve this need. European research of Gruis, Tsenkova and Nieboer (2009) shows that in addition to regulation or subsidies also working on culture change and professionalization of management organisations is of interest. Dreimüller (2008), Gruis (2009a) and Docters van Leeuwen (2009) already recalled that the definition of the ‘volkshuisvesting’ is not an easy task, which is strengthened by the call in the House of representatives in 2009 to Minister Van der Laan to get support within the European Union for the Dutch definition of housing. For European notions are the public-private characteristics and the quality of the housing stock in Netherlands considered as unique. The Dutch State ranks with the availability of social housing on the first place of the 27 Member States of Europe (35% of all houses carry the label social housing) and is at a great distance followed by England and Austria, each with 21 percent. In 18 European countries, the social rental sectorhas less than 8% of the total housing stock.

Cecodas Housing Europe shows in a review in 2012 again what is the balance of social, cooperative and public housing in 27 EU Member States. This is an update of the report Housing Europe (2007). The 2007 study is especially aimed at providing an overview of policy developments in the areas of housing and markets in the social, cooperative and public sector housing. The research Housing Europe Review 2012 (Pittini and Laino 2011) has focused on the way in which social housing systems are structured in the European Union and the developments in the sector. The research gives an answer to questions like, "what is social housing?, how much is the sector? Who are provided with social housing? How is social housing funded? Who has access to social housing? ' The 27 Member States were questioned about these items and are analysed by country. To compare all these countries with the Netherlands is a lot of work, but this is certainly a worthy research. On many points the Netherlands show an exceptional position. A striking example of this is that in the Netherlands social housing, as the highest in Europe, has 32% of the total housing stock. This compares to

Greece where this percentage is 0%. Cecodas Housing Europe is a European Federation of public, cooperative and social housing business, a network of 45 national and regional federations in 19 countries. In total she represents a control of 27 million households. This is about 12% of the existing housing in the European Union.

On the question of European colleagues how it can be that the Netherlands, as one of the richer EU countries, is in need of so much social housing, Netherlands still owes the answer. By defining an iron stock – the number of available homes for the primary target group – and the rest of the housing stock in a subsidiary, a commercial housing stock has appeared. By this model 'Servatius' – named after the Housing Corporation Servatius in Maastricht – (Aedes magazine 2007-4) by extrapolating to the Dutch social housing stock the Netherlands shares a similar place in the rankings as England, Austria, Denmark and the Czech Republic. This would be the solution for preventing the discussion in Europe about the social housing in the Netherlands and State aid, on which European Commissioner Kroes in 2005 from the European Union have previously complained.

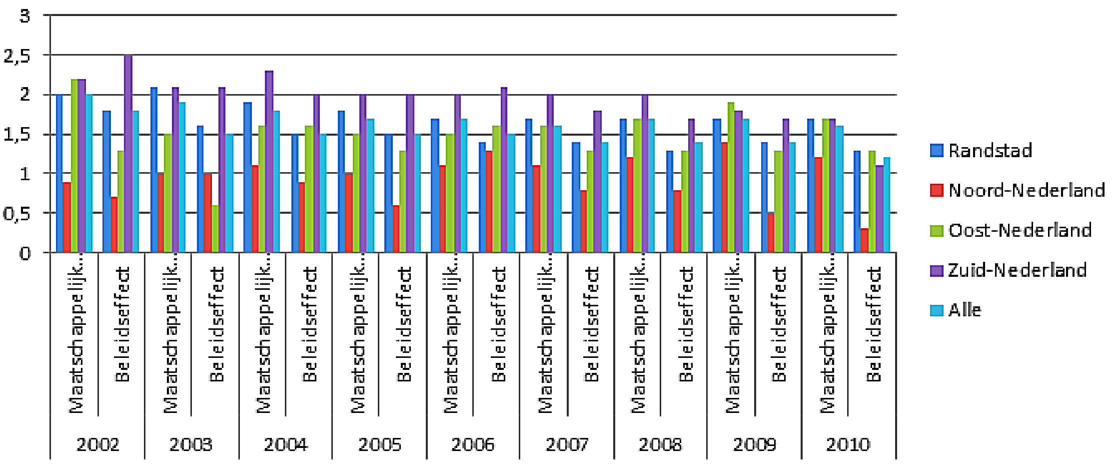
Now the unique position of social housing in the Netherlands is indicated in European perspective, it is important how the performance of housing associations in Netherlands can be indicated in financial and social returns, and what do these returns tell?

5. Accountability with the IPD Nederland Corporatie Vastgoedindex

IPD Netherlands (formerly aeDex) gives the performance of related corporations in returns and is a financial indicator for comparisons (Vlak 2006, 2007, 2009, Konings 2009, Vlak & Den Dekker 2008 en Vlak & Spelbos 2008). IPD is relevant because it aims to create transparency and contributes to further professionalisation of the real estate and investment market. IPD records the returns (Broek 2009) in terms of investment in direct property real estate, that were kept throughout the year. These are so-called standing investments. The independent investment efficiency concerns the so-called gross return on the basis of directly on the management and administration of the objects in the portfolio attributable gross revenue, market value and social management.

It can be concluded that 11% of the number of corporations, have a coverage ratio of 26% in 2009. This coverage ratio has dropped in 2009 compared to the increase in the previous eight years, while the number of properties within the corporations remains stable, according to the indication of IPD. The obvious rise of the size from 2004, which in 2007 and 2008 covered one third of the total home ownership of the corporations has got a relapse of a quarter in 2009, and is thus somewhat at the level of 2004 and 2005. This implies that the importance of the IPD is diminishing. The IPD Property index Corporation (2009) is a guide for the participating Corporation, and functions as a framework on (planned) results. The whole is part of a continuous process of benchmarking. The comparisons among themselves in a certain segment, as well as the analysis behind the numbers, limited to that examined market. The IPD indicates, that the index is just a means of getting information about the financial performance related to return on investment. For example, the policy impact on the primary social portfolio is only in financial and economic terms. The more qualitative choices made are not shown. The policy effect of the IPD also records the effects of the return, arising from the specific items of control. A distinction is made in that part of the portfolio, that is maintained primary with a view to achieving the social goals– the primary social portfolio – and that part for which this does not apply, not the primary social portfolio. The social return is made clear by the real return against what might have been achieved. This under the hypothesis of what could have been fully in line with the prevailing market rent of all properties. That are than the estimated social returns. There still remain two issues about it. First, the condition, that the size of the actual invested capital must be determined and what the minimum required rate of return on that equity should be. Secondly, the question has to be answered, whether the goals set by the company are realized on the basis of the benchmarking that is a reflection on what happened on the market for the participating parties. In Figure 18 the policy effects and the social dividend is shown for the years 2002 to 2010. The effect of the administrative anchoring that homes in the primary portfolio due to social reasons are rented below market rent, is called social dividend. About policy impact is spoken if it is transparent what the yield effects of the realized policy on the non primary social portfolio are. Providing insight into the efficiency effects of realized not primary policy portfolio is defined as policy impact. The policy effect over the period from 2002 to 2009 is measured constantly around the 1.5%. The social dividend for the same period is similar and not significantly different. When the framing-effect (Khaneman 2012:95) is applied it creates the image that 98.5% of the portfolio is not socially profitable.

Figure 2: Policy impact and social dividend 2002-2010 in % efficiency



But what do the comparisons of returns of the IPD tell and are they to be compared? For this research the Dutch IPD figures are put over the period 2000 to 2009 in cross tables with real estate index, efficiency, structure and policy impact. In some cases is chosen to omit certain figures from the cross tables to achieve correct connections. In the tables phases are introduced to indicate that classification and definition have changed over the years. The stages are 1, 2 and 3, respectively, 2001-2004, 2005-2006 and 2007, while the policy over the entire period from 2002 to 2009 has been measured. In and between the different phases are significant differences present caused by definition changes. The figures of the real estate index are processed from 2001 to 2007, over all the years the value over 3 years is annualized and therefore can be considered as a 'common denominator' so closing conclusions can be drawn. The figures for the year 2000 are no longer included in the cross table because the figures from this year are not annualized over 3 years and do therefore not fit in the system of the other years. Reason for this could be that the index in that year has started up and therefore a possible annualization was over more than 2 years. It is striking that in 2007 (phase 3) has been chosen to have only the figures for 2005, 2006 and 2007, and that while after 2001 just about 4 respective 5 years figures are given. A possible explanation is, that the figures were not favorable and therefore were not included in the index. In conclusion, to say that the universe of the IPD Property index Corporation is not frozen. This also means that if a participant or IPD points out inaccuracies in the (historical) data, these will be adjusted. Also are each year participants are added to the index or removed. This means that the IPD Index figures that publishes do not necessarily contain the most current data, although the differences on index level are never big. Remarkable is that data is not frozen. Even more interesting is that at inaccuracies data can be changed. In itself it is defendable that data can be changed due to an error, but the assessment lies with the Corporation that is providing them. And the question then is whether the assessment is correct, or if not (again) can be interpreted differently. But if margins are clear it has no significant impact on final conclusions. Also the actual content of the digits (Hordijk 2005a, Middelhoven 2008 and Hoogen 2010) fits within that framework, because mutations can occur afterwards. Of interest is the tendency of the last ten years and especially in terms of percentages, numbers and participant fluctuation. For the period under review can be concluded that the figures are not significantly different. The problem of constructed historical time series has been acknowledged earlier by Keeris (2005).

6. Conclusions

Findings I - Why this qualitative thesis 'Control of housing associations in consistency with social values'? To understand and to discover patterns about the how and why of the functioning of corporations in society as they do now. This qualitative study is about the search for ideas, backgrounds, motives, resistors and motives and is therefore suitable for the following question: which contradictions are there in the social values that underlie housing associations that affect the way they are governed? The overall summary conclusions to answer the central question is: *Directors, at the highest level thinking about how to deal with values ensure they drive on their own, monitor, know the consequences and take responsibility.*

Findings II - - On the question of European colleagues how it is possible that Netherlands, as one of the richer EU countries, needs so much social housing, the Netherlands still owes an answer. By defining an Iron Stock – the number of available homes for the primary target group – and the rest of the housing stock being put in a subsidiary, a commercial housing stock has appeared. By this model called 'Servatius' by extrapolation to the Dutch social housing stock the Netherlands has about the same level in the rankings as England, Austria, Denmark and the Czech Republic. This would be the solution for preventing the discussion in Europe about the social housing in the Netherlands and State aid, on which European Commissioner Kroes of the European Union has previously complained in 2005.

Findings III – The results of social housing index 2000-2014 MSCI-IPD. Corporations that want to better understand the returns of their portfolio and want to compare their figures to colleagues and competitors can participate in the aeDex / IPD property index corporation. This company comparison system offers corporations insight into their performance as an investor and manager of real estate. The aeDex / IPD property index corporation may make participants visible both their financial and economic and social performance. IPD Netherlands measures periodically the group of participating corporations and compares the results at the organizational level with the aeDex / IPD property index corporation. The aeDex / IPD analyzes the contribution of the various real estate objects to the result, the corporations compares results between themselves and makes comparison with other players in the property market as possible. The real estate index corporation aeDex Foundation aims to preserve the instrument for benchmarking and development through to its member participants.

Serving Building End-Users: Network Positions, Knowledge and the Role of Various Professions

Zehra Waheed[1] and Stephen Ogunlana[2]

Abstract

Built Environment research is beginning to pay more attention towards understanding facility end-user requirements. While this has been more of a focus within construction and architectural research, empirical investigations into how built environment professions serve facility end-user needs have been few and far between. This is due to the customary emphasis on the technical and technological aspects of built environment professions, as opposed to the managerial and social aspects of their work. The primary purpose of this paper is to identify and explore the networked relationships between various building professions during the design, delivery and early occupation of a facility. It reports the findings of an interpretive, inductive case study where network relationships were mapped with knowledge of user requirements being the key determinant of the binary relationships. The principal parties are the users themselves and the various professions serving them. Findings show that during facility design, delivery and early occupation, project sponsor and facilities manager roles remained central to this 'knowledge network'. Users and other professions relied heavily on the knowledge of these two roles. These findings add to current built environment theory by identifying facilities professionals and project sponsors as the two primary roles that can enable the built environment to support the activities of its users. The paper further proposes that only the aggregation of the 'operational' knowledge of building use (held by facilities professionals) and the' strategic' knowledge (held by project sponsors) can lead to a more robust theory of how the built environment can be developed around end-user needs.

Keywords: Built Environment, End-User Requirements, Network, Knowledge, Social Network Analysis

1. Introduction: A User-Centred Theory of the Built Environment

An understanding of building end user needs, whether defined through the customary triple constraint model of project management or through a much wider socio-political lens, is key to the life of successful construction projects. Research shows that an awareness of user needs leads not only to less critical, but also more satisfied clients (Kaya, 2004). It is therefore important that during construction projects, immediate and long term needs of the building users are identified and decisions built upon these throughout briefing, design and delivery of these projects (De wolf and Van Meel, 2002). This paper looks at a co-location (construction) project in the Scottish Borders to develop existing built environment theory on end users. Various built environment professions are mapped using Social Network Analysis with the exchange of building-related knowledge being the determinants of the actors' binary relationships. The theory developed provides new insights and understanding of user-centred theory as defined by Vischer (2008). The purpose is to deepen our sensitivity towards the 'theoretical' in a widely 'practical' field, and to especially develop a more tangible basis of incorporating knowledge of end-user expectations to make building projects more successful.

In the editorial to the special issue of *Building Research and Information* on 'Developing Theories of the Built Environment', Koskela (2008) points out that theory plays a central and crucial role in scholarly activities and also informs public policy concerning the built environment. Koskela notes that built environment theory been fragmented and under-resourced so far. Koskela further notes that built environment theory has also generally been providing the perspective of certain professions or groups, rather than a holistic, cohesive theory addressing the construction and use of the buildings. Koskela (2008) argues that a unified theory of the built environment be developed, especially since most problems associated with design and construction have been the outcome of inadequate theories underpinning the process.

Among theories of the built environment, those that approach users' experiences of built space are extremely important in that they provide a lens to view the creation and management of the built environment to serve the sole purpose of supporting the needs of its end-users. Such user-centred theories then, not only explain the complex relationships between buildings and occupants, but also allow for a more robust measurement of the degree to which built environment has been successful in fulfilling user expectations (Vischer, 2008).

These user-centred theories could generally be categorised on a spectrum of ranging from the macro to the micro. Theory of building use developed around research into the project stages of planning, building and delivery of the buildings, business processes (Cooper *et al*., 2004), building performance evaluation theory (Preiser and Vischer, 2004), building serviceability (Davis *et al*., 1993) and building information systems (e.g. Lutzkendorf and Speer, 2005) for example are theories that provide a larger, all-inclusive lens of building use. The other leg of theories including post-occupancy evaluation (Zeisel, 2006), evidence-based design (Healthcare Design 90, 2006) and the effect of physical features on neural processes (Eberhard, 2007) study the micro-level perspective of specific user needs. Kuhn (2012) notes that neither categories should be seen to be exclusive of each other, as both present different lenses to view the buildings as the means to satisfy users. Furthermore, Green and Schweber (2008) make a compelling case for the development of interdisciplinary middle-range theories that build on micro-phenomenon and connect these to grand theories. The primary purpose of such middle-range theories of the built environment, they pose, is to develop a theoretical response to specific issues: solutions that draw from a wide variety of disciplines and focus on specific, identifiable problems nonetheless.

The theory developed in this paper can perhaps best be categorised as a middle-range theory proposed by Green and Schweber (2008) that brings together a technical tool of representing social relations (Social Network Analysis) with the wider theory of knowledge ownership and sharing and the existing built environment theory on the building end-user. Using a specific context of a socially complex and strategically important co-location project, it links the findings of this one context to develop a better understanding of certain built environment professions in their inherent capacity to engage with and understand the specific (immediate and long term) needs of the people and organisations using buildings. This knowledge of user needs, the paper argues, makes these roles extremely important to the whole building development process.

This paper, which is based upon an inductive, interpretive case study of co-locating higher and further education institutions seeks to address the theoretical gap discussed above, simultaneously addressing the practitioner's need to know which building professions can best identify end-user requirements. This being a necessary step for developing successful buildings.

The structure of the paper is as follows. It begins with a brief review of the existing literature on the significance of knowledge as a means of creating value. This section discusses how knowledge of end-user expectations and needs constitutes a key components of what makes building projects 'successful'. Subsequently, the method of inquiry and the case study is presented. Then the network of key actors is reviewed. This leads to network data analysis and then onto the final section, where conclusions regarding significant built environment professions based on the network of project actors are reached.

2. Knowledge of User Requirements

The 'end users' can be defined as those who occupy or use the building. These persons may not be the experts at managing the buildings, but have knowledge and opinions about its performance in relation to their own objectives (Kaya, 2004; Lai and Yik (2007). A common characteristic of successful building projects is successfully meeting end-user requirements. This user satisfaction contributes to much wider benefits to the client organisation through sustained loyalty to the firm, repeat purchase, increased market share and profitability (Mbachu, 2003). The widely cited Latham Report (Latham, 1994) published by the UK government had reasoned that an important cause of built spaces falling short of client expectations was that construction professions usually designed and executed projects with environmental constraints, longevity and aesthetics in mind rather than the need of the user-clients. Such an observation either postulates that the construction professions involved either lacked clear knowledge of client's needs, or those professions which do have clear insights usually retained a less central role in the construction process. Either way, it is important to identify professions that hold the key to knowledge regarding built environment use.

The significance of knowledge as the means of creating value in the organisation has also increasingly come to the fore in management literature especially in the past fifteen years (Schreyogg and Geiger, 2007). Knowledge is now considered a significant resource (David and Foray, 2002) with knowledge work emerging as a dominant theme in the context of the knowledge economy (Robertson *et al*., 2003; Alvesson, 2004). Related concepts focus on the growing significance of social capital (Tsai and Ghoshal, 1998) the need to leverage knowledge assets (Newell *et al*., 2002) and improving the accessibility of knowledge (Rifkin, 2000). This literature establishes the significance of knowledge and knowledge sharing processes as the means of value creation.

Knowledge of end-user expectations and needs constitutes a key components of what makes building projects 'successful'. Hence its 'value' to the organisation undertaking the project, as well as the developer/ consultant is immense.

3. Case site and Research Methods

The AB co-location case study presented here is part of a much wider exploratory case study undertaken to assess a number of theoretical questions. The objective of this particular enquiry was to use Social Network Analysis in a mixed-method design to explore wider underpinnings of knowledge sharing within a project system. While the unit of analysis for the wider study was the project itself, the unit of analysis for the analysis presented in this paper is the 'core network' of also built environment professions and other managers which constituted of nine project actors identified by the 'ego' (the most central actor) in the wider network of the entire project, constituting of 52 project actors. The 'ego' was the individual with the most central location in the project network, with the widest number of ties with other actors and hence was in the best position to identify key project players.

The case site was a construction project of a co-locating campus undertaken by two established Scottish educational institutions: one Further Education (FE) institution and the other a Higher Education (HE) institution. Org-A is an FE institution while Org-B is an HE institution. The co-location project, now complete, was undertaken under the Scottish Executive's 'Shared Services Initiative', the purpose of which was providing better financial value FE/ HE through modern, shared, co-located facilities to replace outdated, dispersed campuses. Within the new campus, which jointly hosts both Org-A and Org-B, most of the physical infrastructure (services and spaces such as the libraries, catering, common areas and classrooms) was designed as shared areas for both Org-A and Org-B. However, within the campus, each institution continues to maintain its own autonomy as a separate entity with separate spaces for staff, research students, administration and specialist laboratories and teaching areas.

Apart from the advantage of providing a wider scope of academic collaboration across subject areas common to both institutions, both organisations saw this project as the means to offer far superior facilities and services to both students and staff, than what might have been possible for any single institution to provide on its own. As the new campus fulfilled the 'shared services' aims of the Scottish Executive's policy initiatives, this co-location was partly funded by the Scottish Funding Council (SFC), which remained an important stakeholder throughout the life of the project. For these reasons the project was perhaps the most important physical undertaking for both institutions quite possibly for the next decade.

Apart from the differing end-user they serviced (in terms of a different student and faculty body)- since Org-A was a further education body and Org-B a higher education institution- Org-A and Org-B were vastly different in terms of size and organisational structure as well. Org-B was physically dispersed over different campuses, and had an estates function with one senior management person was attached to each of its campus locations with responsibility for the estates, facilities, and services. Org-A, on the other hand, was a large organisation with a multi-tiered organisational structure. Although its presence in the region was small, it had a layered organisational structure with a high powered Director of Estates formally responsible for the management of all campuses and estates and a Director of Campus Services (who was supported by a formal in-house facilities services team) responsible for the campus in question.

The case site was studied during its final completion year and post-occupancy (Figure 1), however the data used in this paper was collected prior to full occupancy: hence capturing relational data during the development of the buildings, a requisite aim of the enquiry.

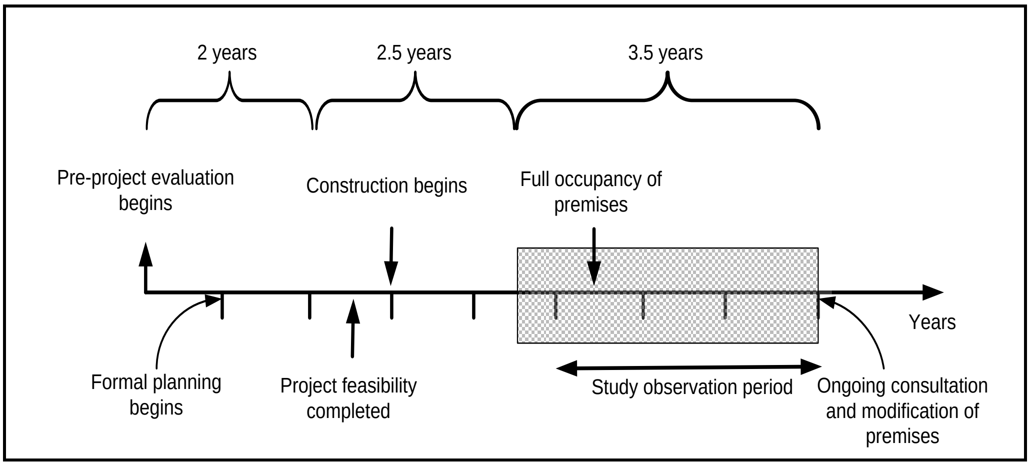

Figure 1: Timeline of the case

Key actors in the co-location project identified by the 'ego' in the wider project network were those with a high value as sources of knowledge. Together, these nine actors were identified as the 'core network' of the project. These actors were the Vice Principal (Org-B), Director Planning (Org-B), Director Campus Services (Org-B), Director Finance (Org-B), Building Surveyor, University Secretary (Org-B), Project Sponsor (Org-A), Project Manager and the Principal (Org-A). Questionnaires were then distributed among these primary actors and their responses solicited regarding their interdependencies and knowledge of:

- Real estate and strategic needs of organization (knowledge area 1)
- Operational requirements of the buildings (knowledge area 2)
- Human and environmental factors in buildings (knowledge area 3)
- Planning and project management involving built facilities (knowledge area 4)
- Facility and service delivery (knowledge area 5)
- Communication (knowledge area 6)

Knowledge area 6 was added as a particular knowledge area since practitioners find great difficulty in making end-users see a longer-term perspective as well as overcoming cultural barriers to understanding real end-user needs (Pemsel et al., 2010). Both these challenges can be overcome through effective communication and hence the profession with the superior knowledge of communication channels and structures was better equipped to be able to engage with the end-users.

4. Network Data and Analysis

Previous efforts on capturing relationships of built environment professions holding key knowledge of users has typically been limited to pre-identified professions in the project. Pemsel *et al*. (2010), for example, focuses on three players only: end users, end users project manager (EPM-which they define as a selected end user) and the facility planners (FP). This paper, however, uses a case study of a complex, phased co-location project of two Scottish educational institutions (one Further Education, the other Higher Education) and maps 52 key players and their dyadic knowledge-dependent relationships identified through interviews with stakeholders. The mapping is carried out using Social Network Analysis (SNA), which is a method of exploring social structures through the use of network and graph theories. SNA describes networked structures in terms of nodes (individual actors, people, or organisations within the network) and the ties (i.e. relationships or interactions) connecting these nodes or actors. A broad majority of social network studies either use the “whole network” or the “egocentric” design. The first: whole network studies, examine sets of interrelated actors that are related. Egocentric studies, on the other hand, focus on a focal person and the relationships in its locality (Marsden P., 2006). The matrix representation of this common form of network data is known as a “who to whom” matrix or a *sociomatrix*. The results presented in this paper follow the whole network design where the ‘core network’ is identified from a wider network of the entire project. Data regarding knowledge sharing (the relationship) between and primary actors is developed. The data obtained was directional and valued (i.e. the flow of knowledge had a direction and the collaborative tie had an intensity assigned by the recipient actor), and the analysis was carried out using the Ucinet 6 software (Borgatti *et al*., 2002).

The data on the level of collaboration and knowledge sharing (collaborative relationships) between the key actors was collected using a questionnaire. The other eight key actors comprising the core network were the other eight ‘alters’ identified by the ‘ego’ of the wider network of 52 actors. By ‘collaborative ties’ the research means the existence and strength of knowledge-sharing between the key actors on issues related to the six knowledge areas identified. Each questionnaire respondent was asked to identify the other ‘alters’ in the core network with whom they discussed, shared or developed knowledge relating to any of these FM competencies. The responses were not dichotomous (dichotomous responses are binary, with a value of 0 or 1, showing only the existence or non-existence of a tie) but valued (where respondents placed a value between 0 and 5 on their knowledge sharing ties with the other ‘alters’) and directional (where knowledge sharing relation had an origin and a destination). This ego-centric core network had nine actors, i.e. N=9, where N was the total number of nodes in the network.

$$N = \{n_1, n_2, n_3, n_4, n_5, n_6, n_7, n_8, n_9\}$$

The lines between the actors (for example line $l_{1,2}$ between n_1 and n_2) as shown in figure 3 and 4 depict the degree of reliance of n_1 on n_2 for building-related knowledge. Line $l_{1,2}$ depicts the degree of reliance of n_2 on n_1's expertise. Figure 3 shows only the ties, while Figure 4 shows the ties and the *strength* of the tie i.e. the intensity of knowledge dependency on a certain actor, for knowledge area 3: Human and Environmental Factor.

The sociomatrices for each of the knowledge areas were valued and non-symmetric and took the following form shown in Figure 2 below:

		1	2	3	4	5	6	7	8	9
		1	2	3	4	5	6	7	8	9
1	1	0	4	5	0	0	3	0	0	0
2	2	4	0	5	4	1	3	4	1	3
3	3	4	4	0	3	4	4	4	2	4
4	4	3	2	5	0	2	4	5	2	5
5	5	0	1	5	2	0	0	3	2	2
6	6	0	1	5	1	3	0	1	0	2
7	7	0	3	4	2	1	1	0	3	5
8	8	0	0	0	0	1	0	1	0	0
9	9	0	4	5	3	0	0	4	0	0

Figure 2: Sociomatrix for Knowledge Area 3-Human and Environmental Factors

Similar sociomatrices were developed for each knowledge area. Two digraphs (the graphical representation of the relational data) for the above adjacency matrix of knowledge sharing of human and environmental factors are shown below. The first diagraph (Figure 3) shows only the direction of the knowledge sharing without tie strength (i.e. the intensity of the relationship). The second diagraph (Figure 4) is a valued graph, with the thickness of the lines depicting the tie strength between the actors. Figure 4 is obtained by adding the tie strength data to the diagraph in Figure 3. The arrows (in Figure 3) depict the flow of knowledge and line thickness (in 4) depicts the tie strength of the collaborative relationship. Similar digraphs were created for all knowledge areas.

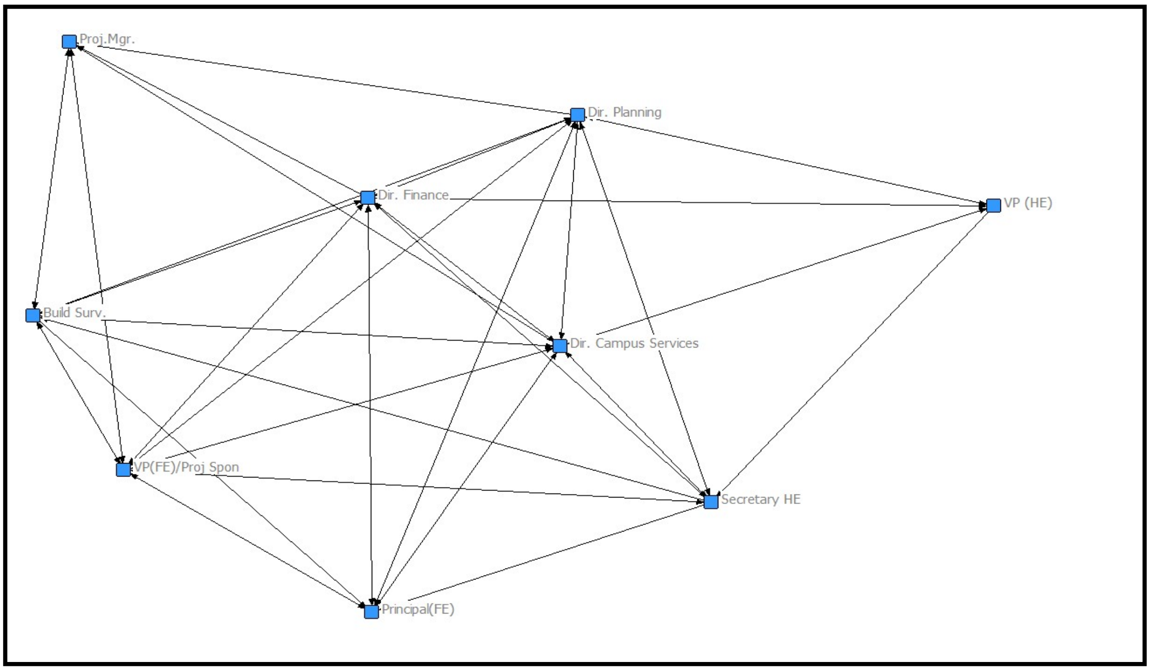

Figure 3: Diagraph of Knowledge Area 3 (Human and Environmental factors)

The analysis of the 'human and environmental factors' knowledge area is discussed here in detail. What is immediately evident from Figure 3 is the fact that despite the core network being a closely knit unit, not all actors were approached by others as sources of knowledge. Human and environmental concerns are a vital component of any workplace and the individuals that contribute to decisions relating to it, inevitably affect workplace usage, social interactions and overall user experience. In the core network, certain actors for example the vice principal of Org-B and the construction project manager were not sources of knowledge for this particular competency. At least five or more other actors said they had never approached these actors for human and environmental issues. They were, nevertheless, important for the knowledge sharing process supporting the overall decision-making process during design and construction. On the other hand, the network analysis shows that there were certain individuals who were repeatedly approached for expertise related to knowledge of human and environmental factors and were approached by almost all actors in the core network. These were the Project Sponsor (Org-A) and the Director of Campus Services (Org-B). The degree of reliance on these individuals for human and environment-related knowledge was consistently given a very high value by other actors. Two other actors, the Director of Finance (Org-B) and Principal (Org-A) were also approached by six other actors. However the degree of reliance on them for expert knowledge was considerably lower.

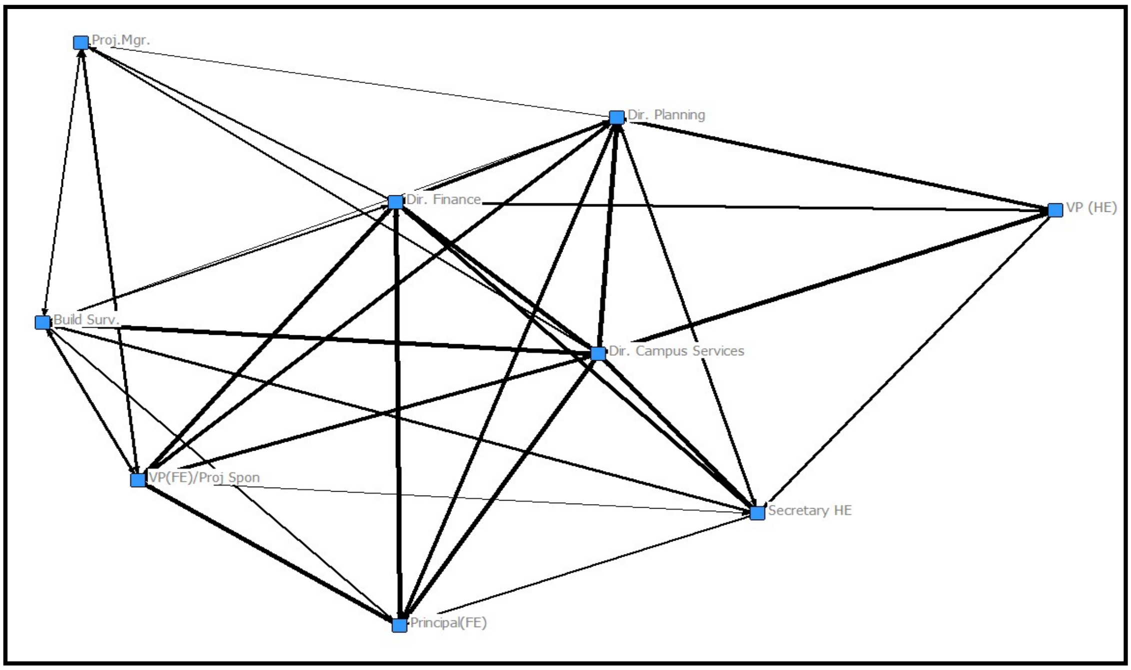

Figure 4: Diagraph of Knowledge Area 3 (Human and Environmental factors) with tie strength

Figure 4, which shows the tie strengths, provides a visual picture of the intensity of collaborative ties between the members of the core network for this competency. Interestingly, the ties are also strongest for the four individuals noted above, who were the primary sources of human and environment-related knowledge during the co-location project. This finding shows that together not only were these individuals a source of expertise to others, but that they remained close to each other for collaboration and to complement each other's knowledge relating to this competency.

Similar findings, with varying degrees of tie strengths were found for the other five knowledge areas. Table 1 below gives a synopsis of the findings from the sociomatrices and diagraphs of all the six knowledge areas, including competency 3 discussed above. In the table, a single 'X' denotes a low status as source of knowledge for each of the FM competency areas, while an 'XX' denotes a high status as a source of knowledge for each of the FM competency areas for an actor.

Table 1: Individuals with high value as sources of knowledge

	Vice Principal (Org-B)	*Director Planning (Org-B)*	*Director Campus Services (Org-B)*	*Director Finance (Org-B)*	*Buildin g Survey or*	*Universit y Secretary (Org-B)*	*Project Sponsor (Org-A)*	*Project Manag er*	*Principal (Org-A)*
K 1	*X*	*XX*	*XX*	*X*			*XX*		*X*
K 2			*XX*				*XX*	*X*	*X*
K 3			*XX*	*X*			*XX*		*X*
K 4		*X*	*XX*	*XX*	*XX*		*XX*	*XX*	*XX*
K 5			*XX*	*X*	*X*		*XX*		*XX*
K 6		*X*	*XX*	*XX*			*XX*	*X*	*XX*

A comparison of the various digraphs (not shown here) demonstrates that while differences existed across different knowledge areas, overall the core network had close knowledge sharing and collaborative ties. Nevertheless two individuals, the Director of Campus Services (the top facilities manager) and the Project Sponsor (senior manager responsible for the overall success of the project) remained central as sources of vital knowledge for all competencies. These two actors were also the individuals with the strongest ties with other actors in the core network. The analysis of the wider whole network (not shown here) also showed that these two individuals were strong ‘connectors’ between the other actors in the whole network as well (i.e. some actors would have been totally disconnected from the rest of the network were it not for these individuals). The analysis of the core network’s relationships primarily showed the emergence of two individuals as critical disseminators of building -related knowledge and a clear indication by other actors that not only were the top facilities manager and project sponsor the source of expertise for real estate strategic planning, but also operations, communication, the management of the entire project, facility service delivery and environmental factors.

In order to investigate the direction of knowledge sharing, the research also computed the nodal degrees of the knowledge sharing phenomenon within the core network (see table 2). The ‘degree’ for a node, defined as the total number of relationships involving that node and it permits comparisons between network participants. Individuals with higher degree values are more active than those with lower values. The ‘indegree’ for a node is the number of relationships in which a particular node is the target (in this case, approached for certain building-related knowledge). Both nodal degrees are measures of a node’s connectivity with other nodes: the higher the node degree, the higher its connectivity. Again, the two actors: the facilities head (Director of Campus Services) and the project sponsor (Vice Principal, Org-A) came out as the leaders when it came to being the source of building-related knowledge for all core network actors. The implications of these findings are discussed in the conclusions section.

Table 2: Nodal Indegree of actors in the network

	Vice Principal (Org-B)	Director Planning (Org-B)	Director Campus Services (Org-B)	Director Finance (Org-B)	Building Surveyor	University Secretary (Org-B)	Project Sponsor (Org-A)	Project Manager	Principal (Org-A)

5. Discussion and Conclusions

As discussed earlier, established theories of the built environment tend to be either product-oriented (how the building and its associated services function post-completion) or process oriented (how buildings are procured and produced). In neither set of theories do end-users play a pivotal role. A likely gap in built environment theory, therefor, exists around the nexus of end-users, perhaps due to the 'technical' focus of built environment research that does not capture softer, human aspects of the context. It is therefore important that built environment theorists make a conceded effort to capture the perceptions, needs and expectations of facility end-users in order to develop a coherent, integrated theory that assimilates end-users into previously developed theory. The widely cited Latham Report (Latham, 1994) has also reasoned that an important cause of built spaces falling short of client expectations was that construction professions usually designed and executed projects with environmental constraints, longevity and aesthetics in mind rather than the need of the user-clients. Such an observation either postulates that the construction professions involved either lacked clear knowledge of client's needs, or those professions which do have clear insights usually retained a less central role in the construction process. Either way, it is important to identify professions that hold the key to knowledge regarding built environment use.

This paper therefor asserts that one way is to identify built environment professions/ roles that best capture end-user requirements- be they related to strategic real estate needs of the organisation, operational requirements of the buildings, human factors affecting building design and use, the planning and execution of building projects, or the facility and service delivery during the operational life of these built assets. The analysis of network data presented in the previous section helps built environment theory by identifying certain professions and roles that remained pivotal in knowledge dissemination (leading to policy and strategy development as well as project execution) related to several aspects of end-user needs within the core project network. The findings from the network analysis show that during facility design, delivery and early occupation, project sponsor and facilities manager roles remained central to this ‘knowledge network’. Users and other professions relied heavily on the knowledge of these two roles. These findings add to current built environment theory by identifying facilities professionals and project sponsors as the two primary roles that can enable the built environment to support the activities of its users. The paper further proposes that only the aggregation of the ‘operational’ knowledge of building use (held by facilities professionals) and the’ strategic’ knowledge (held by project sponsors) can lead to a more robust theory of how the built environment can be developed around end-user needs.

The findings help develop an understanding that certain built environment professions (the project sponsor and the facilities head) in their inherent capacity to engage with and understand the specific (immediate and long term) needs of the people and organisations using buildings, can be pivotal in developing a closer understanding of end-user needs throughout the life of the construction and occupancy of built assets.. This inherent knowledge of user needs makes these two roles extremely important to the whole building development process.

These findings support earlier theory developed within facilities management domain such as McLennan’s (2000) work which argues that building (or facilities) knowledge that has strategic value is that which pertains to its understanding of the relationship between the performance of physical resources and the customer/ end user being served. Pathirage *et al*. (2008) view such knowledge to be vastly tacit in nature and assert that it is necessary for facility managers to realise that they hold the unique information on the physical resources and their use over time. In their proposed Intellectual Capital Framework for FM, FM’s knowledge capital is the outcome of the knowledge it derived from strategy, systems and assets (‘structural capital’); customer’s orientation and market positioning (‘customer capital’); and the knowledge and capabilities of individuals to provide solutions to facility customers (‘human capital’). Together this knowledge base, they argue, can be used to create value for the organisation. The findings from practice, presented in the paper augments this key role of facilities managers. The role of project sponsors as carriers of important tacit knowledge regarding end-users has been less explored in theory and this research must be taken forward to explore this aspect further.

Abstract

Many countries around the world are in search of new means to engage the private sector in managing and financing infrastructure through Public Private Partnerships (PPPs). However, most of the PPPs have faced issues during design and concession period. When considering Australian context Stakeholder Management (SM) related issues have been reported as one of the main reasons for failure in several instances. PPPs involve many stakeholders whose interests might not be in agreement leading to conflicting objectives. In such situations SM has a high level of importance to avoid the conflicts and to achieve the success of projects. Therefore, this research aims to determine the current emerging issues related to SM in Australian PPPs and to investigate the strategies to cope with those issues. Mixed methods of research were adopted in this research. Initially critical review of literature was undertaken followed by 19 semi structured interviews and a questionnaire survey. The findings revealed twelve critical issues related to SM. A variety of SM strategies to cope with the critical issues were also established. The proposition that the Government sector is better equipped to manage the general public involving in economic decision making was further confirmed via the findings. Also the findings insisted the necessity of a strong Government in managing the stakeholders of a PPP project. Nonetheless in reality the Government tries to transfer the entire SM risk to the private sector.

Keywords: Public-Private Partnerships, Stakeholder Management, Issues, Government

1. Introduction

PPPs are a popular form of major project procurement for the delivery of building and infrastructure facilities. Service contracts, management contracts, lease contracts, build operate transfer and similar arrangements, concessions and joint ventures are some different formats of PPPs (Felsinger, 2008). According to Grimsey and Lewis (2002), achieving value for money in the services delivered and allowing the private sector entities to meet their contractual obligations are the primary objectives of using PPPs in delivering public infrastructure. PPPs have become a popular method to procure infrastructure projects in Australia. The PPPs in connection with building and infrastructure procurement constituted around 5% of the new investments in Australia in 2009 (Chan et al., 2009).

However, Johnston (2010) highlighted many implementation issues in Australian PPPs. The Sydney Cross City Tunnel, the Southern Cross Station in Melbourne and the Southbank Technical College and School are some examples where the public has been disappointed which leaded to adverse publicity for the Government and commercial losses for the private sector (Wilson et al., 2010). Johnston (2010), Hodge (2004), Siddiquee (2011), Johnston and Kouzmin (2010) and Regan et al. (2011) pointed out many issues in Australian PPPs. Some of these issues in border context can be viewed as: lack of transparency of the PPP arrangements, lack of monitoring during the operations, lack of collaboration between the public and private parties, lack of trust towards PPPs, political agenda towards PPP projects and lack in addressing the interests of the general public. These issues can be directly associated with ineffective SM practices. Similarly stakeholder opposition towards the PPPs has been reported as one of the main reasons for the failed PPP projects globally (El-Gohary et al., 2006, Siemiatycki, 2009, De Schepper et al., 2014, Smyth and Edkins, 2007). As such the issues related to SM should be further explored to investigate the strategies to cope with those issues. Chinyio and Akintoye (2008) confirmed the importance of SM in the modern forms of construction procurement such as partnering and private finance initiative. Accordingly many stakeholders are involved in this process whose interests are not always likely to be in agreement. According to a report published by World Bank, the first factor out of seven major points that are holding up private investment in infrastructure is the wider gap between the Government and the private sector interests (De Schepper et al., 2014). However, according to De Schepper et al. (2014) these stakeholder issues do not merely emerge because of this gap but due to the concerns related to ineffective SM approaches. Despite the literature have suggested proper SM a systematic SM framework for PPPs is yet to be developed in addressing the current emerging issues in PPPs.

The objective of this paper is to address the aforementioned gap and contribute to the knowledge base of SM in PPP projects by presenting findings regarding the current emerging issues in the Australian PPP market. Also to propose a list of SM strategies in addressing the current emerging issues. This study is part of a larger research project which aimed at developing a SM framework for PPP projects in Australia. The next section will discuss SM implications in PPP environment highlighted by previous studies. Then it will explain the research methodology of the study followed by research findings and the discussion of the findings. Finally some conclusions were drawn.

2. Stakeholder Management Implications in PPP Environment

2.1 SM in PPPs

SM concepts continued to evolve from general management to construction project management literature. Many authors have highlighted the importance of stakeholder consideration in construction projects. Assudani and Kloppenborg (2010) and Cleland (1998) suggested that success in construction projects significantly depends on meeting the needs of stakeholders. Bourne and Walker (2005) and El-Gohary et al. (2006) highlighted that stakeholders play a decisive role in construction projects which can make or break a project. Before discussing the SM in PPP project environment it is worthwhile in defining SM in a project. Rowlinson and Cheung (2008) provided a definition for SM by using the studies undertaken by Brammer and Millington (2004) and Pajunen (2006). Turner (2003) and Yang and Shen (2014) also provided definitions for SM. According to these scholars this research defines SM as “A process of identifying, negotiating, engaging stakeholders and developing relationships among stakeholders to achieve minimum project risks and facilitating projects to deliver the project timely and effectively.”

El-Gohary et al. (2006) initiated the development of a SM model for PPP projects. This semantic model was developed to capture and incorporate stakeholder input in the design. But according to Henjewele et al. (2013), the proposed semantic model is too complex to adopt in real projects and has only focused on the design stage. Also this model has only concentrated on the public involvement process of PPPs. Henjewele et al. (2013) developed a SM model for the whole life of a PPP project which insisted the importance of incorporating the ideas of the general public. However this model is too generic and has not considered the actual level of complexities associated with the PPP procurement structure. Ng et al. (2013) and Ahmed and Ali (2006) also highlighted the importance of considering the people as partners. Ng et al. (2013) developed a framework for the successful public engagement. Majamaa et al. (2008) also did a study on how to build the fourth P into the PPP process using some case studies in Finland. However no study has focused on exploring SM related issues and the strategies to cope with those issues. These SM strategies will help to develop a proper SM framework for PPPs. To achieve the main aim of this study it is worth to investigate the issues highlighted by the previous studies that are directly related to SM practices.

2.2 Lessons from Recent Experience in PPPs in Australia

Political agenda towards these infrastructure project decisions have created many issues from the start of several PPP projects in Australia. According to Siddiquee (2011), the Sydney Cross City Tunnel project was politically advantageous in a PPP structure and in reality the way it was structured didn’t produce the best outcomes. Lack of information dissemination to the public is another critical issue identified in the wider PPP literature (Linder, 1999). While general public tend to ask for more information of PPP projects, the Government had to maintain a balance of what information to be disclosed and what are commercially sensitive. This has become problematic in many cases and led to citizens’ distrust towards these infrastructure developments. Serving the wider community is one of the main objectives of using PPPs in infrastructure development. However, Wilson et al. (2010) highlighted that the Sydney Cross City Tunnel, the Southern Cross Station in Melbourne and the Southbank Technical College and School are the examples where the interests of the general public are not well addressed. Johnston (2010) highlighted another critical issue as longer-term performance monitoring is lacking in the Australian PPPs which is often need to sustain the defence of the long-term operational viability or success of a PPP versus traditional procurement. Further Siddiquee

(2011) pointed out that there is no sufficient staff capability for the PPP delivery. According to Kwak et al. (2009) this can lead to tensions between public and private partners and, if not remedied, it could lead to project failure. Another critical issue is the conflicts between the public and the private partners are not well managed. According to Johnston (2010), this may affect the core value of PPPs and potentially represent a major, but usually silent, pitfall within the model.

Table 1 summarises the above issues in PPPs explored by the previous studies. Most of the issues in Australia have been echoed by the authors in global context demanding urgent research efforts. All the above issues can be directly related to SM practices of a project. For example political agenda deals with stakeholder interests and effective stakeholder analysis might help to solve those issues to a greater extent (De Schepper et al., 2014). The issues related to the general public interest also can be directly related to SM as public engagement is one of its major components (Leung, 2010). Performance monitoring issues also can be directly associated with SM practices as it involves following-up the strategies and actions that have been implemented (Karlsen, 2002). Staff training aspect and conflict resolutions are two of the major components of SM framework of a project (Yuan et al., 2009).

Table 1: Summary of the issues in PPPs

Issue	*Johnston and Kouzmin (2010)*	*Siddiquee (2011)*	*Regan et al. (2011)*	*Johnston (2010)*	*Wilson et al. (2010)*	*De Schepper et al. (2014)*	*Kwak et al. (2009)*	*Henjewele et al. (2014)*	*(Jepsen and Eskerod, 2009)*	*(Koppenjan, 2005)*	*(Saengsupavanich et al., 2012)*

3. Research Methods

3.1 Data Collection & Analysis

The eight SM related issues explored by the literature review were discussed in the previous section. Subsequently semi structured in-depth interviews were adopted as means of further investigating the SM related issues in the Australian context. Also to explore the strategies to cope with the SM related issues. At present nineteen semi-structured interviews were conducted. Due to the involvement of multiple numbers of stakeholders in a PPP project, we stratified the sample into two professional groups to obtain the public and private professional insights into the research questions. Respondents were selected randomly by contacting the Government Departments and the private companies that have dealt with a variety of Australian PPPs. Successively a questionnaire survey was conducted to further evaluate the criticality of the identified issues from the literature review and the interviews. The online survey tool ‘Qualtrics’ was used to distribute the survey. Stratified and random sampling was again used. The survey was distributed to the contact lists in public and private company websites which have dealt with PPP projects in Australia. Additionally, many respondents were found from the LinkedIn social network where pools of professionals get in to contact. In order to identify the relative significance of SM related issues for different stakeholders, Likert-style rating questions, using a five-point scale. The scale intervals in this research can be interpreted as follows: (1) not critical at all; (2) not critical; (3) Neutral; (4) critical; (5) extremely critical. Overall, 357 responses were received of which 341 were valid and used for further analysis.

The interview results were analysed using the content analysis via NVIVO software. The questionnaire data were analysed using the IBM statistical package SPSS22 soft-ware. Initially descriptive statistics such as mean and standard deviation were used. The responses given by the respondents were tested for the null hypothesis (i.e. that means between groups do not differ significantly) using non-parametric tests suitable for small and unequal sample group sizes. As such the Mann–Whitney U-test can examine the level of agreement. The null hypothesis is that the mean significance of each factor is equal between any two groups. If the value of U exceeds its critical value at some significance level (0.05), there is evidence to reject the null hypothesis.

3.2 Analysis of the background of respondents

The interview participants were all senior managers involved in the bidding, construction and operational phases of PPP projects. All of the interviewees had more than five years’ experience in any type of PPP project with some SM experiences. 10 Panel members represented the private sector, 5 the public sector where as 4 have involved in both the sectors. Considering the questionnaire survey 37% of the respondents had more than ten years of professional experience and 32% had more than 5 years of experience. Also nearly 50% of the respondents had the exposure for 2-5 number of PPP projects. Therefore, the respondents can be considered as well experienced in this field. There were representations covering both the private and public sector views. Figure 1 shows the sample structure for the interviews and the questionnaire survey respectively.

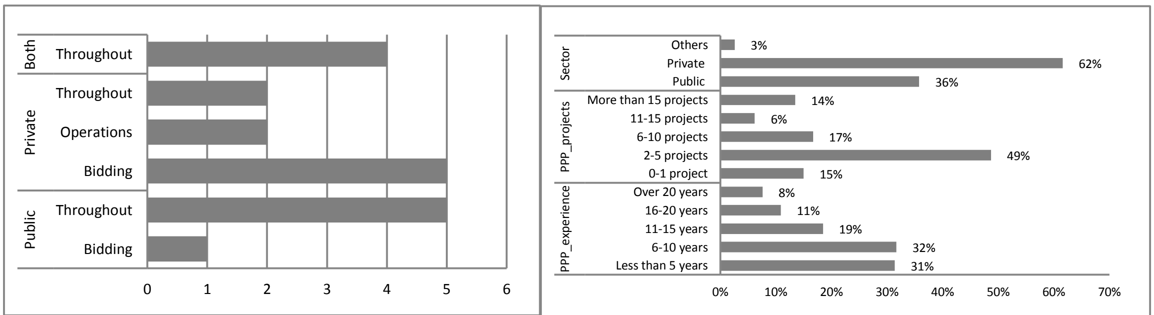

Figure 1a: Sample structure (interviews) *Figure 1b: Sample structure (survey)*

Figure 1: Sample structure

4. Research Findings

4.1 SM related issues in PPPs

Table 2 summarises the interview and the questionnaire survey results. It shows the number of interviewees agreed for each of the issues. Also it reports the mean response rating values for the questionnaire survey results. After the interviews four new issues (Issue_3, Issue_4, Issue_5 and Issue_7) were added into the SM related issues identified from the literature review. Interview respondents agreed that all these issues are critical in PPP environment. One interviewee highlighted that it is essential to identify the issues in the past projects and implement corrective actions from a SM point view. Considering the questionnaire survey results no mean value scores fell into the 'extremely critical' (4.50) and 'not critical at all' (1.5) categories, which indicates that all of these 12 issue are critical for each group.

Both the interview and survey results have confirmed the Issues_4 is critical in Australian PPP environment. This was captured from one of the interviewee representing the private consortium. Accordingly they are interacting with multiple Departments when working on a PPP. However, these departments provide contradicting information which has leaded to many conflicts within the partnership. The Issue_6 is a well-recognised issue in the wide PPP literature. Interviewees highlighted that most of these PPPs are in existence due to a political party pushing through for its political gain. And they stressed that in reality this decision should be longer term economic and social decision rather than political. The representatives from the private consortium explained the Issue_5 as, the project brief and the reference design prepared by the Government is not sufficiently comprehensive leading to many issues during the operations. Regarding the Issue_12 the interviewees highlighted that there are many loopholes in the PPP contracts which have leaded many conflicts. Therefore, they underscored the importance of the relationships between the parties to the contract demanding urgent research effort for proper strategies to improve the strength of relationships. Private sector consortium members were desperate about the Issue_2 and they urged the need for more stakeholder engagement by the Government. Issue_7 was recognised from the interviewees representing the private sector. Accordingly there is a lot of nervousness around the financiers due to the current conditions in Victoria (the fact that the Government could change at any point in time). This has leaded to less financial support for the PPP development process. Interviewees from both the sector highlighted that as the PPP concept is fairly new to Australia there is a lack of sufficient resources to manage these projects (Issue_11). Also the interviewees highlighted that some of the managers consider moving on to the operations as the focal point of these projects. However they stressed that it should not be the case. Therefore they stressed the issue of lack of monitoring during the operations (Issue_10). Further the interviewees from both the sector highlighted the difficulty in forecasting the stakeholders and their interests throughout the project life cycle especially due the long term nature of these projects (Issue_1). The Issue_3 and Issue_9 have reported low mean values as opposed to the literature review and the interview results. For example the Issue_9 was a well-recognised issue in literature and also the interviewees confirmed it. One of the interviewees highlighted that there are many PPP projects that have pushed into the industry without considering the needs of the general public. Although the questionnaire survey reported low mean values for these issues they are in acceptable level with a mean value above 3.0 and therefore considered as critical.

Table 2: The SM related issues in PPP projects and their scores and rankings in different groups

Code	Issue	Interview results	Questionnaire Survey Results						
			Overall		Public		Private		P-value
		No of agreed interviewee	Mean	Rank	Mean	Rank	Mean	Rank	
Issue_4	Responsibilities overlap between different Government agencies	15 out of 19	3.70	1	3.63	2	3.75	1	0.343
Issue_6	Political interests push PPP project decisions rather than social and economic	19 out of 19	3.66	2	3.65	1	3.67	2	0.723
Issue_5	Incomprehensible project brief and reference design leads to uncertainties	16 out of 19	3.44	3	3.27	4	3.56	3	0.044
Issue_12	Not efficiently managing conflicts between the private and Government	17 out of 19	3.44	4	3.25	6	3.56	4	0.011
Issue_2	Lack of early stakeholder engagement	13 out of 19	3.43	5	3.25	5	3.52	5	0.049
Issue_7	Financier's nervousness due to changes in the Government	14 out of 19	3.40	6	3.29	3	3.46	6	0.190
Issue_11	Lack of staff capability in the PPP project delivery	15 out of 19	3.23	7	3.16	7	3.26	8	0.516
Issue_10	Lack of monitoring in stakeholder needs and issues during operations	18 out of 19	3.18	8	3.09	8	3.25	9	0.236
Issue_1	Difficulty in identifying stakeholders and their interests throughout the PPP life cycle	15 out of 19	3.15	9	2.94	11	3.27	7	0.004
Issue_8	Lack of information dissemination to public	17 out of 19	3.09	10	3.02	10	3.14	10	0.233
Issue_3	Not disclosing the history behind PPP project to the private consortium	16 out of 19	3.02	11	2.80	12	3.14	11	0.004
Issue_9	Interest of the general public is not well addressed	15 out of 19	3.01	12	3.11	9	2.96	12	0.645

Reliability analysis is conducted to test the internal consistency of the survey variable data. Cronbach's alphas are 0.853. It is much higher than the 0.70 of Nunnally's guideline (1978). The results of reliability tests show that the stakeholders agreed on most of the SM related issues. However, there are some disagreements reflected by the scores and rankings in different stakeholder groups. For example, the mean and the ranking of the issue "Issue 12" is higher for the private sector when compared with the public sector. However it is important to investigate whether these differences are statistically significant. Therefore, Mann–Whitney U-test was used to explain these disagreements between stakeholder groups. The test results of pairwise comparisons between public and the private sectors are summarized in Table 2, which indicates that there are significant differences in the opinions between groups for the issues "Issue 6", "Issue 7", "Issue 8", "Issue 9" and "Issue 11". All these issues have become critical for the private sector side of the partnership.

4.2 SM strategies for PPP project success

Interviewees were asked to propose some improvement measures to cope with the above identified SM related issues. The following section will discuss the strategies proposed by the interviewees for each of the issue.

The interviewees emphasized the importance of having a good understanding on each others objectives in a team. Appointing an independent party to monitor the stakeholder matters during initial stages was another recommendation. Representatives from the private sector proposed that extensive initial consultation by the Government will help to understand the stakeholders and their needs more sensibly. These were proposed to address the Issue_1. The following were proposed to address the Issue_2. Both the sectors highlighted the need for extensive stakeholder engagement during the initial stages by the Government. Also the private sector representatives highlighted the necessity of participating in the very early information sessions conducted by the Government. The interviewees from the private sector proposed to maintain a register of all commitments made to stakeholders before bidding by the Government sector to address the Issue_3. Accordingly that register should be shared with the project company within the tender. Also the private consortium members proposed to have a process to streamline the overlaps between different Government agencies (Issue_4).

As the project brief and the reference design prepared by the Government is not sufficiently comprehensive (Issue_5) the representatives from the private sector urged the need to have more certainty within the Government's tender document. Most of the interviewees couldn't give a solution to cope of the Issue_6. They highlighted that the political forces are a pain for them. The interviewees from the private sector highlighted that the Government should approach PPPs with honesty. Further they proposed that the Government can follow a by-partisan approach to the stakeholders through engaging with all political parties during bidding. The private sector representatives proposed to provide regular updates to the financiers to cope with the Issue_7. Also more engagement with the state before approaching the financiers is also recommended.

The private sector participates proposed to improve the websites allowing people to access the information easily, to communicate clear information to general community at the correct time and to make the independent reviewer's opinion available to the general community to improve the transparency of the project (Issue_8). Interviewees highlighted the importance of the Government's role in protecting public interest (Issue_9). The interviewees urged the necessity of engaging with the general public during the initial stages. The interviewees highlighted many improvements to cope with the Issue_10. The representatives from both the sectors proposed to develop more KPIs related to SM and to measure the KPIs via stakeholder surveys. Also they proposed to monitor the stakeholder relationships during operations. And they advocated the importance of proper issue escalation process to efficiently address the stakeholder issues. Regular strategic stakeholder meetings and on site engagement meetings were suggested. The interviewees from the Government proposed to appoint an independent party to monitor the stakeholder matters during operations. They highlighted the need to embed the SM into business case and contract manuals.

The representatives from both the sectors proposed to create a system which accumulates the lessons learnt via regular stakeholder workshops to cope with the Issue_11. Also providing training for the people who are working around PPPs is also important. SM experts highlighted that the project directors do not see the clear advantages of SM to a project. As such they advised to expose project managers into real cold phased stakeholder issues. The representatives from the private sector highlighted the importance of developing comprehensive reference designs in dealing with Issue_12. This will lead to fewer conflicts during the construction and operations. Also the interviewees highlighted the need for more stakeholder engagement by the Government sector at the very initial stages. Moreover they proposed appointing an independent party to monitor the stakeholder matters during the initial stages.

5. Discussion

The issues identified from the literature review and the interview results were further validated via a questionnaire survey. “Responsibilities overlap between different Government agencies” and “political interests push PPP project decisions rather than social and economic” have become the most critical issues based on the mean score ranking. Interview results also confirmed that “political interests push PPP project decisions rather than social and economic” is the most critical issue related to PPP projects. Further according to the interview results “lack of monitoring in stakeholder needs and issues during operations” and “not efficiently managing conflicts between the private and Government sectors” are the second most critical issues. Questionnaire survey also confirmed that these issues are critical with a mean score value of 3.18 and 3.44 respectively. Surprisingly although the literature review and the interview results confirmed that all the issues are very critical to PPP project success, questionnaire survey have reported few low mean values for some of the issues. However all the mean values were above 3.0 and considered that all these issues are critical.

The Government and the private sector parties had common opinions on the criticality of some of the SM related issues in PPP projects. However there are evident differences as well. As shown in Table 2 most of the issues have become critical for the private sector when compared with the public sector. “Difficulty in identifying stakeholders and their interests throughout the PPP life cycle at the bidding stage”, “non-disclosure of the history behind PPP project to the private consortium”, “incomprehensible project brief and reference design leads to uncertainties”, “lack of early stakeholder engagement” and “not efficiently managing conflicts between the private and Government sectors” have become critical for the private sector. “Non-disclosure of the history behind PPP project to the private consortium”, “incomprehensible project brief and reference design leads to uncertainties” and “lack of early stakeholder engagement” are directly associated with the activities related to the Government sector side of the partnership. As “not efficiently managing conflicts between the private and Government sectors” has become a critical issues to private sector it can be viewed that the Government should become the main driving party in managing the conflicts of a PPP project. As such these results highlighted the importance of the Government sector role in SM for PPPs. One interviewee from the private consortium also confirmed this point in relation to public engagement as *“… then the Government has someone to blame if the community is not happy with the outcome. But we have no control over the public benefit of the project as we are not the once who created those projects.”* Further it was noted that in reality the Government is trying to transfer the total SM related risk to the private consortium. Chung et al. (2010) confirmed this point in relation to risk management in PPP projects in Australia. As such the findings insisted the importance a strong Government with robust SM practices for successful PPP projects.

The identified issues and strategies proposed were summarized and assigned into the sector that is mostly relevant. The following Figure 2 summarizes the findings. Accordingly most of the issues and the strategies identified are related to the government sector side of the partnership. This finding also confirmed the importance of the Government sector role in managing stakeholders.

	Issues	Reccomendations
Government	• Lack of early consultation with all stakeholders (by the Government agency) • Political interests push PPP project decisions rather than social and economic • Lack of information dissemination to the public • Not disclosing the history behind PPP project to the private consortium • Incomprehensible project brief and reference design leads to uncertainties • Responsibilities overlap between different Govt. agencies	• Maintain a register of all commitments made to stakeholders before bidding • Share the register of all commitments with the private consortium • Communicate clear information to general community at the correct time • Allow private consortium to participate in information sessions conducted by Govt. • Improve Govt. websites allowing people to access the information easily • Govt. agency engages with general community to develop tender doc • Govt. makes the independent reviewer’s opinion available to Public • Allow private consortium To engage with all political parties during bidding • Ensure the responsibilities do not overlap among different Govt. agencies
Both	• Difficulty in identifying stakeholders and their interests throughout the PPP life cycle at the bidding stage • Lack of monitoring in stakeholder needs and issues during operations • Not efficiently managing conflicts between the private and Government sectors • Lack of staff capability in the PPP project delivery • Interest of the general public is not well addressed	• Be honest with general community • Develop more Key Performance Indicators (KPIs) related to stakeholder management • Measure possible KPIs via stakeholder surveys • Appoint an independent party to monitor the stakeholder matters during initial and operations • Monitor relationships of stakeholders during operations • Create a system which accumulates the lessons learnt via regular stakeholder forums • Embed stakeholder management into business case, procurement and contract manuals • Establish issue escalation process to efficiently address stakeholder issues • Regular stakeholder meetings and on site engagement meetings during operations
Private	• Financier's nervousness due to changes in the Government	• Early involvement of the financial institutions

Figure 2: Overview of the issues and the strategies proposed by the interviewees

6. Conclusions

Both the interview and the questionnaire survey results investigated 12 critical issues related to SM in PPPs. It is necessary to address the current emerging issues related to SM in the research agenda. The comparative study between the private and the Government sector highlighted some differences in the views on the criticality for some of the issues. And it was noted that most of the issues have become critical for the private sector side of the partnership enquiring improvements in the Government sector. As such, the findings insisted the importance of a strong Government sector in dealing with SM for PPPs. However in reality the Government is trying to transfer the total SM risk to the project company leading to many confusions and issues in the later stages. This study emphasised an urgent research interest to develop a set of strategies to improve the SM related to the Government sector side of the partnership. Interview results identified a variety of strategies to cope with the SM related issues in PPPs. These strategies should be further validated from a questionnaire survey which is currently in progress. This study is part a larger research project which aimed at developing a systematic framework for SM in PPPs.

Uncovering the Real Needs of Customers

Evelien Klasens and Mieke Oostra

Saxion University of Applied Sciences, Netherlands
Email: e.klasens@saxion.nl

Abstract

In this paper an inventory will be given of methods and tools currently available in the construction industry and other sectors to make the needs and wishes of clients explicit, in order to incorporate them into the design, engineering and building process. In order to be able to create value from a client's point of perspective, it is necessary to find out what really matters to clients and what their real needs are. However, professionals in the construction sector with a genuine interest in making needs and wishes from clients and customer organisations explicit, know this is not an easy task. In contrast with the field of construction, it is more common practice in most industries to involve all different stakeholders in order to make requirements explicit. There are also different methods and tools available, which leads to the question what tools are most effective and reliable to discover requirements? Research in the domains of marketing, cognitive linguistics and psychology shows that customer needs can't be clarified by expression in words alone. A lot of choices are made unconsciously, without the use of language. Important associations people have can be made visible by using metaphors or pictures. These insights from other sectors can be of advantage to professionals in the construction industry. Based on this insight evaluation criteria are formulated to assess the available methods to uncover requirements. Based on the outcomes of this evaluation an improved tool is proposed, in which pictures are used to unravel customer needs.

Keywords: requirement engineering, MCDM+, stakeholder requirements, photo elicitation

1. Introduction

It seems an easy job; to collect the requirements for a new building. Just ask the stakeholders what they want, write it down in a programme of requirements and translate it into a design. But even when we spent a lot of time talking to stakeholders[1] , about their needs and wishes, it is still a difficult job to develop something that will meet all the requirements. On the one hand this happens of course because there are a lot of different stakeholders with often conflicting requirements and it is impossible to develop something that will meet all demands. But on the other hand are we able to uncover the necessary requirements with the methods we use in construction today? Looking at research into current failure costs it becomes visible that a large part of these costs is caused by bad or a lack of information. Recent research in the Dutch building sector shows that sloppy information exchange and a lack of communication are the most important causes of high failure costs (almost 11% from the total returns) (USP Marketing Consultancy BV, 2010). Getting the right information and sufficient data will help to decrease these failure costs. This starts with clear information on what it is end-users, clients and other stakeholders want. How can we make sure we get the right information on stakeholder requirements? What are the questions behind the questions when clients demand a specific building? What are the underlying motives? And which tools are the most effective and reliable to discover the requirements? To answer these questions additional research is needed, therefore the following research question was formulated: What are efficient ways to discover the real requirements and needs of stakeholders, based on what we know on the functioning of customers (unconscious) minds from marketing research, cognitive linguistics and psychology? In order to be able to make a proper inventory of stakeholder requirements in an efficient manner, research was conducted into what is known about the functioning of customer's minds. This knowledge was used to formulate criteria to evaluate the different methods[2] used in construction and in other sectors on this aspect. This evaluation is presented in section 3.4.

2. Inside the customer's mind

According to marketing expert Zaltman (2003), most marketing managers operate from a paradigm – a set of assumptions about how the world works – which prevents them from understanding and serving customers effectively. In the construction sector we seem to have the same problem. Professional clients think to know what the requirements of the users are, but quite often when the building is realised, it appears that it does not meet the users' needs in the

[1]When the term "stakeholders" is used in this paper, the different users of the building (employees, visitors, cleaners, etc.) are meant, as well as the parties involved in het development process of a building (e.g. architect, municipality, fire department, contractor, electrician).

[2]Tools used to visualize the requirements found are beyond the scope of this paper and are not discussed.

way it was intended. One of the reasons this happens is that people don't understand how their own and their customers minds interacts. We can explain this by taking a look at figure 1 (Jastrow, 1900). At first you'll see a rabbit or a duck. What you will see the first is different from person to person. This demonstrates a very important point; two people can look at the very same information and have two totally different interpretations (Jastrow, 1900). Miscommunication can come into existence quite easily. This is one of the reasons new

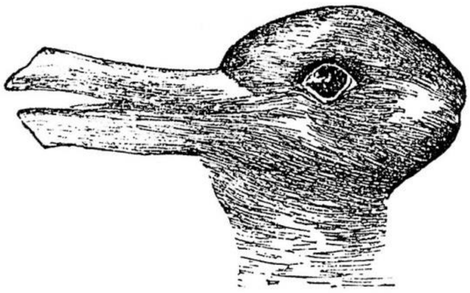

Figure 1: Duck-Rabbit (Joseph Jastrow, 1900)

buildings do not always fit the needs of the users of the building. It occurs even when developing parties can and do involve the users and other stakeholders. In a lot of cases however, they are not even invited to participate, or are not involved on a regular basis, so their needs are not even heard. Jerome Kagan, a professor of psychology at Harvard University, is regarded as a key pioneer in the field of developmental psychology. According to him ninety-five percent of our thinking takes place in our unconscious mind. Therefore the selection process is relatively automatic and is influenced by social and physical context (Kagan, 2002).

Most people also think that people's thoughts occur in terms of words. They think they can find out how people think by using standard interviews or questionnaires. Of course, words do play an important role in expressing our thoughts, but they don't outline the whole picture. This leads to the question, if the methods currently used to uncover needs are the right ones and the most effective ones. It seems smart to make more use of people's unconscious thinking and decision making. This means that we shouldn't use 'words' alone to find out what the real needs are, but also use pictures to tap into emotions and to discover needs. On top of that, decisions in construction are often quite complex and not transparent. Usually the client does not know what exactly they will get from the contractor or architect. "Human thought arises from what neuroscientist call images. Words can trigger our thoughts and enable us to express them. That's why people believe that thought occurs largely as words" (Zaltman, 2003). Metaphors often help us express the way we feel about important aspects in life (Zaltman, 2003; Johnson & Lakoff, 1980). "We have found, on the contrary, that metaphor is pervasive in everyday life, not just in language but in thought and action. Our ordinary conceptual system, in terms of which we both think and act, is fundamentally metaphorical in nature." (Johnson & Lakoff, 1980). Researchers who make use of photo elicitation (PEI), which is mostly used in social and anthropology studies, also support this view. Therefore Marisol Clark-Ibáñez concludes in her paper "Framing the Social World with Photo-Elicitation Interviews" that using the PEI alone or in combination with other methods such as interviews or observations can discover insights that wouldn't be found when using other approaches.

Based on this information on the functioning of our brains, we formulated the following criteria to evaluate existing methods to reveal stakeholder requirements:

1. *Taps into emotions*; are the instruments fit to pinpoint the emotions that drive the stakeholders involved?
2. *Closes the content gap*; can part of the method close the interpretation gap that exists between stakeholder and the person who is conducting the workshop/interview/discussion (caused by different experience, backgrounds, education)?
3. *Uncovers the underlying motivation*; is the method able to reveal the underlying motivation of the needs of the participant/stakeholder?
4. *Gives depth and detailed information*; can the method provide detailed information about the requirements of the participant/stakeholder?
5. *Breaks into the unconscious part of our brain*

3. Existing methods to explore customer needs

Different methods are used in various sectors to uncover the needs and requirements of users when developing products or services. Basically the questions that developers have and the information they need are the same, only the approach to gather this information sometimes differs.

3.1. Popular methods in the construction sector

When new buildings are developed, requirements of end-users are often filled in by the client. Although sometimes methods from other industries are used to explicitly investigate those, the methods most commonly used in the construction sector are described below. The advantages and disadvantages of the methods are listed in table 1.

Surveys

Surveys are also regarded as an easy way to discover needs and requirements. It’s a frequently used method in many different industries. With the use of surveys a lot of people can be reached to gather a substantial amount of information, that enables researchers to extract general conclusions valid for a large part of the population.

Interviews

Interviews are frequently used as a user requirement gathering method. This method is also used to discover the requirements of other stakeholders. Interviews can provide a lot of important information. Aspects that can cause problems or result in wrong conclusions when conducting interviews are that stakeholders and engineers usually have different backgrounds, experiences, and expectations from the system-to-be (Burnay et al, 2014).

Focus groups

A focus group is a special group of people in terms of purpose, size, composition and procedures. The purpose of a focus group is to get more insights in how people think and feel about a certain subject, idea or service. The group discussion is repeated several times with similar types of people. The aim is to find trends and patterns in the perceptions from the different participants (Krueger & Casey, 2015).

Multi Criteria Decision Method (MCDM)

The MCDM is a new tool in the construction sector, initially introduced to come to an Integrated Building Design (IBD) for new construction projects in which the environmental issues are addressed properly. The selection and prioritisation of design criteria among stakeholders at the beginning of the project is considered crucial (Balcomb et al, 2002). Additionally alternative design solutions should be evaluated in the process in relation to these criteria. The MCDM method is developed to assist in both. With this method it becomes possible to make the requirements of the different stakeholders explicit by discovering what is important to the different departments of the client organisation. It starts with a discussion to formulate priorities for the organisation as a whole, thereby transferring detailed information on what has value to the parties that will design, engineer and construct the building. Since the introduction in 2002 this method is also used for refurbishment projects (Alanne & Klobut, 2003; Hofman et al, 2012) . The MCDM is therefore an instrument that is developed to clarify and prioritize the different aspects that are important to clients and end-users. The MCDM-discussions starts with a list of major aspects (Hofman et al, 2012). Valuable aspects are divided in sub-themes in order to make the different facets from a specific aspect explicit for the client. Subsequently the importance of the aspects are indicated by marks. The higher the mark, the more important the aspect is in the eyes of the entire client organisation. Finally the outcome will be a map of the most important aspects and their priorities (Hofman et al, 2012).

3.2. Methods from other sectors

In other industries they use different methods whereby also visualisation is used. These methods are described below. In table 1 an overview can be found of the strengths and weaknesses of each method.

Photo elicitation

Photo elicitation is used in anthropology and sociology. Basically photo elicitation is the introduction of photographs into an interview. Compared to standard interviews, it can be noticed that people respond differently when photos are shown. Interviews whereby photos are used not only produce more information, but also different kinds of information, because images evoke deeper elements of human consciousness than words are capable of (Harper, 2002).

Metaphors

In the IT sector the requirements elicitation process is quite difficult, because it’s often about a new sort of system and specifications hereof that has not been built before, as is also the case in construction. In this sector metaphors are often used to find out what the real users' needs are. A metaphor is an imagery and suggests a similarity between two things or ideas that are not equal in reality. Metaphors therefore help to better understand unknown abstractions (Visscher et al, 2005).

Personas

What working with personas is, can best be described with a citation from Sim and Brouse (2014): "The concept of persona is an emerging new paradigm in user requirements modelling. Personas are fictitious and concrete representations of a specific group of target users. Personas are constructed to resemble real people. Personas contain information about the users' names, ages, occupations, educational backgrounds, knowledge, abilities, interests, goals, concerns, usage patterns, environment the users engage in, and so forth."

Some might expect Systems Engineering (SE)to be included in this overview. SE is a method that is commonly used in Civil Engineering and is used more and more in the development process of buildings. With Systems Engineering more time is required in an early stage of a project. First all the stakeholders will have to be identified and the project team will determine if and how the stakeholders should participate in the project. This creates support for the project and it helps to clarify all requirements. An important aspect of Systems Engineering is the requirement analysis for which usually standard methods are used such as interviews, surveys and focus groups. This means that all the information is gathered by verbal methods. It is therefor not a method in itself that is used to determine the requirements in the initial phase only, but more like an overall approach that is used throughout the development process as a whole. This is the reason SE is not included as requirement gathering method in this paper.

3.3 Evaluation of the methods

To determine the value and appropriateness of the different methods, the strengths and weaknesses are listed in table 1.

Table 1: Strengths and weaknesses of requirement gathering methods

Instrument	***Strengths***	***Weaknesses***
Survey	- *Delivers a lot of data* - *Fit for questioning large groups of people* - *Fit to derive conclusions valid for a large group of people* - *Less social desirable answers* - *Cheap*	- *The results are incomplete and not always correct, because 95% of our decision-making is unconscious* - *Not able to uncover the underlying motivation of people* - *No in depth information* - *No influence on the response* - *Often a low response* - *Additional questions for clarification are not possible* - *Most of the time answers are predefined*

Interview	- *Provides detailed information* - *You can ask additional questions to get more information*	- *The results are incomplete and not always correct, because 95% of our decision-making is unconscious* - *Not appropriate if you are looking for information from a large sample of the population* - *Can take significant time to conduct* - *Interviewer and stakeholder will probably have different backgrounds, experiences and expectations (Burnay et al, 2014)*
Focus groups	- *Will gain insights in how people think and feel* - *Provides information quickly with low costs* - *Researcher can interact directly with the participants* - *Possible to obtain rich and large amounts of information* - *People can react and build on responses by others* - *Flexible (Krueger & Casey, 2015)*	- *The results are incomplete and not always correct, because 95% of our decision-making is unconscious* - *Participants in a group are inclined to give socially appropriated answers* - *Will not tap into emotions, while emotions are the key drivers of behaviour* - *Participants can feel forced to make up answers when they don't know the answer* - *Results can be trivial* - *Dominant participants can influence the outcomes (Krueger & Casey, 2015)*
MCDM	- *Contradicting needs and interests will become transparent* - *Provides insight in what is most important to clients and why* - *Gives insight in what the client really wants* - *Leads to better communication and understanding between the different departments in an organisation* - *Helps to structure the requirements within user organisations* - *Helps to prioritise the different requirements (Hofman et al, 2012)*	- *Costs more time in the initial phase of the project* - *Can be difficult to keep the main question in focus therefore experienced moderation is important* - *Can be difficult to clarify all the different aspects that are important to the client* - *Providers think in technical specifications and solutions (can lead to misunderstanding or miscommunication)* - *It is really hard for the representatives of client organisations to represent the organisation as a whole (Hofman et al, 2012)*
Photo elicitation	- *Images evoke deeper elements of human consciousness that words do* - *With photos the unconscious part of our thinking is stimulated* - *Better and more reliable information* - *Provides more detailed information (Pommeranz et al, 2011)*	- *Finding useful photos can be difficult* - *Using unsuitable photos can be harmful* - *More time consuming then standard interviews (Pommeranz et al, 2011)*
Metaphors	- *Helps to understand unknown abstractions* - *Are dynamic* - *Deliver a collective conceptual reference model* - *Suggest features and sometimes relations*	- *The client can interpret the metaphor in a way that is not anticipated* - *Problems can occur due to cultural differences.* - *The search for the right metaphor can be a difficult process (Visscher et al, 2005)*

	- *Clients and developers are talking on the same level* - *Metaphors can break through existing thinking patterns* - *Metaphors makes us use multiple parts of our brain (Visscher et al, 2005)*	
Personas	- *More focus on the end-user, their tasks, goals and motivation* - *Leads to better design solutions* - *Make the needs of the end-user more explicit* - *Strengthen the focus on the end-user, their tasks, goals and motivation* - *Can improve communication* - *Facilitates more constructive and user-focused design discussion (Long, 2009)*	- *Considerable resources are required* - *Developing personas costs a lot of time and effort* - *A scaled-back or low-budget version of personas can be harmful* - *If details and goals of the persona are not correct then the alignment of the design can be inappropriate* - *Requires training at an organisational level (Long, 2009)*

If we compare different requirement gathering methods, it can be concluded that surveys and interviews aren't the most useful methods to discover the real in depth requirements. Surveys will only help to get a general view of needs. Interviews can be used to get more detailed information, but both methods give only insight in the conscious thoughts of people, while actually information about the unconscious motives of people can be much more valuable. Burnay et al (2014) also conclude that a standard interview doesn't provide all the necessary information to develop an optimal system (in this case a building). Although focus groups will gain more insights in how people think and feel by participating in a group discussion, it still doesn't tap into their emotions. People are inclined to give socially appropriate answers. Often people are unaware what really drives their behaviour. Many decisions are non-rational and often emotional responses to circumstances. According to Barry Feig (as cited in Krueger & Casey, 2015) emotions are the key drivers of behaviour. Most people are not aware of the emotions that influence their behaviour. In a focus groups it is hard for the moderator to get to relevant insights. The MCDM method seems therefore a better method to make the requirements of the client organisation explicit. It also leads to better communication and understanding between the different departments in an organisation and between the organisation and the suppliers. Another strong aspect compared to some other methods is that this method helps to prioritise and structure the requirements. This will finally result in a building that meets the needs and requirements better than it would be when the building was developed in a traditional way. Despite the fact that it makes requirements more clear and transparent, it still is a method that makes use of words only. This means that there is still hidden information that will not come to the surface. Pommeranz et al (2011) concluded in their paper "Elicitation of situated values: need for tools to help stakeholders and designers to reflect and communicate" that standard methods (for example interviews and surveys) don't provide the real life context needed for people to understand and express their values. They have compared different methods and concluded that photo elicitation seems well suited to uncover real values. They tested the method by using a normal questionnaire and a photo elicitation interview. The most detailed information came out of the photo elicitation interview (Pommeranz et al, 2011). With photos or images you can stimulate the more unconscious part of our thinking, which leads to more accurate and more reliable information. While most projects in construction are rather complex and meant for a long lifespan, we should not exclusively use linguistic methods to uncover needs. Making use of pictures or photos can help to get more insights into the real needs, and it provides more detailed information, which will automatically lead to a better understanding. During requirements elicitation clients and developers often have the problem that they don't understand each other. The client thinks in organisational and business terms, while the engineer thinks in technical terms. To close this gap metaphors can be an appropriate tool (Visscher et al , 2005). This communication gap, as it is referred to in the IT sector, also exists when developing buildings. Yet metaphors are not or rarely used in the construction sector. They are used in the design, but not in the initial phase of a project where the first requirements are gathered. The construction parties speak a more technical language and think mostly in technical solutions, while the client and other stakeholders think and communicate in other terms (organisational or financial). Besides, another related problem is that clients generally do not really know the requirements of their end users. The client also speaks another language than the different user groups, so there's another gap. Metaphors can help to break through existing thinking patterns and can also help to talk on the same level. Because of that metaphors stimulate us to use multiple parts of our brain, there for more detailed and reliable information can be gathered. Sim and Brouse (2014) claim that by empowering the concept of personas into requirement engineering activities, a greater comprehensive understanding of the users' needs and behaviours can be realized early in the requirements engineering process, thus allowing engineers to identify missing demands. According to Long (2009) there is more focus on the end-user, on their tasks, goals and motivation. It makes the needs and requirements of the end-user more explicit. Using personas therefore could be helpful for the requirement analysis when developing buildings.

3.4 Evaluation of existing methods

In the multi criteria analysis in table 2 the different methods and the five criteria are listed as introduced in chapter 2. For every criteria a method can score on a scale from 0 – 5. 0 means that it doesn't apply at all and 5 means that it strongly applies.

Table 2: Multi criteria analysis existing methods

	Tap into emotions	*Closes the content gap*	*Uncovers the underlying motivation*	*Gives depth & detailed information*	*Breaks into the unconscious*	***Total score***
Survey	*0*	*0*	*0*	*0*	*0*	***0***
Interview	*2*	*0*	*3*	*3*	*0*	***8***
Focus groups	*1*	*0*	*4*	*4*	*0*	***9***
MCDM	*2*	*3*	*4*	*4*	*0*	***13***
PEI	*4*	*2*	*5*	*4*	*5*	***20***
Metaphors	*4*	*4*	*3*	*4*	*5*	***20***
Personas	*2*	*4*	*3*	*3*	*2*	***14***

When looking at the mca, it can be concluded that the survey is the most ineffective method to discover customer needs. It will not provide detailed information and is thus not useful in finding out the underlying motivation. Utilizing interviews is a bit better, but also with this method it is hard to tap into emotions and it still doesn't trigger the unconscious part of our brain. The methods that really do break into the unconscious part of our brain are the photo elicitation and the metaphors. Since these methods break into the unconsciousness part of the brain, these two methods also have a high score in 'tapping into emotions'. These two criteria make them score a lot better than the other methods to reveal customer needs. Because most of what we do or decide occurs unconscious, an effective method should tap into this decision process.

A lot of stakeholders are involved when developing buildings. Not only the requirements of individuals are important, also the requirements of different departments or user groups is needed. Therefore not only individual information should be collected, but also information from groups. Photo elicitation or the use of metaphors are worthwhile methods to get the needed information from the individuals, but a different method is needed to disclose information of groups. Looking at the strengths and weaknesses of all the methods evaluated in this paper we see that especially the 'visual' methods (using metaphors and photo elicitation) have a lot of important advantages that really contribute to better end results. Besides that, there are not a lot of weaknesses known from these methods. The weaknesses that are mentioned can be prevented. Personas also have a lot of strengths that could contribute to better results, however, attention should be given to known weaknesses. Developing personas is already a project in itself and cost a lot of time and effort. Using photos or metaphors is therefore to be preferred. This is also proven in other sectors e.g. the IT sector, anthropology and sociology.

3.5 MCDM+

Based on the conditions described above a new tool is evolving. The general aim is to develop a tool that triggers the unconscious parts of the users minds to get better and more valuable information about the real needs and requirements from different users. At first the focus is on professional end-users of a building. The tool should also help to articulate the needs of specific client groups consisting of the different departments of an organisation by making use of photos and pictures, since needs and requirements within an organisation depend partly on the activities, working methods and subcultures within the different departments. Because the MCDM method does this, it makes requirements more explicit and helps to prioritize them, it is chosen as a basis. When this method is combined with a tool that addresses the unconscious part of peoples thinking, a more complete and wider supported set of requirements can be made. This new method is called MCDM+. A first concept is ready and has been tested in two workshops during the 2015 edition of the LEAN Construction Symposium in the Netherlands with sustainability & lean as central theme.

Aim

The main aim is finally to give insight into the needs of different organisation departments to arrive at a shared view of the needs of an organisation as a whole, including the most relevant priorities therein. An important part is to give insight into the differences and provide understanding of each other's motives and point of views. To get a total list of all the requirements, the tool should be used in several rounds to discuss different topics. In the tests of the concept method the topic 'sustainability' was addressed.

How the tool is used

(1) For each subject there is a large amount of pictures related to the subject (at least 30). Every individual collects a maximum of five pictures that symbolises the main aspects concerning this topic from his or her point of view. When choosing the pictures the person should reflect from his or her function and department, but personal preferences should also be ventilated. (2) People from the same department show each other the pictures chosen and explain to each other why they have chosen these and what it is they think matters. (3) When every member of the group has done this, they discuss were the similarities and differences appear. (4) The group put the pictures that symbolises the most relevant aspects for them as a group on a large piece of paper and clarify (e.g. with different colours, text, drawings and clustering of pictures) their motivation. (5) In the next step each group presents what the topic, in this case 'sustainability', means for them as a department. The most important differences between the departments will start to emerge in this stage. (6) Finally, when all groups have presented, the moderator will try to reach consensus about the most important priorities of the organisation as a whole on this specific topic.

4. Summary

An evaluation was made in this paper of the methods that can be used to make an inventory of stakeholder requirements. Considering the methods that are used to discover stakeholder needs in the construction sector, we can conclude that methods commonly used in construction only make use of words and verbal communication. Using these methods leaves a lot of important information undiscovered. This clarifies for an important part the inability to meet the needs of the users and other important stakeholders. Construction parties and clients are not able to tap into the unconscious level of stakeholders' minds, even when they are focused on involving important stakeholders and put a lot of time and effort in the start-up phase and the requirement analysis with Systems Engineering. While the final outcome of this process may have less shortcomings, usually only linguistic methods are used, thereby missing important information which results in an incomplete listing of requirements. Knowing that most information rests in the unconscious parts of our mind, unable to come out with verbal research methods, this isn't really surprising. Looking at the evaluation of seven existing methods, four from construction and three from other sectors, the construction industry could benefit from the use of photo elicitation and/or metaphors to discover requirements. Using photos and metaphors seem to be a welcome addition to the existing methods in construction, because they can gather more specific and reliable information and help different parties to communicate on the same level. This is really an important issue, because a lot of problems and failure costs are caused by miscommunication and a lack of information exchange between the different parties. In order to improve this a new method was developed: MCDM+. The MCDM was used as a basis, combined with the use of pictures, thereby ameliorating the requirement gathering process to reveal in a more complete and supported set of requirements.

Abstract

It has been widely acknowledged that failing to address occupant needs and expectations has severe negative effects on the outcomes of building retrofitting efforts, resulting in a performance gap in energy saving as well as occupant satisfaction and productivity. When evaluating performance metrics such as occupants' thermal comfort, indoor air quality, space use and control by occupants, literature indicates a particular success of occupant feedback in comparison to the code defined standards and physical measurements since no assumptions is made and all contextual influences are taken into account. Analysis of the existing post occupancy evaluation tools, however, reveals the lack of an empirically validated and structured framework to measure occupant satisfaction with a holistic approach embracing different aspects of occupant comfort. In this paper, as a first step in developing the occupant satisfaction measure, occupant satisfaction dimensions and indicators in the literature have been reviewed systematically and organized in a hierarchical structure to ensure content validity of the model. Occupant satisfaction was configured under eight dimensions and under each dimension, the related indicators were identified. In addition, possible sources of dissatisfaction for each indicator were determined from the literature, which are intended to be used for determining the needs of the occupants and priority areas to focus on in the pre-retrofit phase.

Keywords: Retrofit, occupant satisfaction, post occupancy evaluation, office, workplace satisfaction.

1. Introduction

The commercial building sector is widely accepted as the sector with highest potential for energy savings (Tobias and Vavaroutsos, 2009; DOE, 2012; Ma et al. 2012; Jazizadeh et al., 2014; Azar and Menassa, 2015). The energy demand of commercial buildings is growing faster than any other economy (Azar and Menassa, 2015) and is expected to grow by more than 20% by 2035 (EIA, 2003). To reduce the environmental impacts of buildings, the construction industry is undergoing a transition toward the development of a more sustainable built environment, often called as green buildings (World Green Building Council (WGBC), 2009). Riley et al. (2004) defined a green building as ‘the one that minimizes resource consumption during design, construction, and over its life, and provides healthy and productive environments for occupants through the application of sustainable principles’.

The green movement initially focused on the design and construction of new buildings and importance of energy efficiency improvements in existing building stock (retrofitting) have been underemphasized (Tobias and Vavaroutsos, 2009). During the last decade, however, it’s been realized that retrofitting existing buildings have even more significant effect on the total energy demand since many of the buildings in 2050 are the ones that exist today (McGraw-Hill, 2009; Ma et al. 2012; Asadi et al, 2013). Today, retrofitting is considered as the key approach to realistically achieving substantial energy saving in building sector and many governments and international organisations have put significant effort towards energy efficiency in existing buildings (Ma et al. 2012). Research has shown, however, that especially commercial and office buildings may show higher-than-expected energy consumption levels, even when energy-efficient building systems are installed in the retrofit process (Azar and Menassa, 2015). This ‘performance gap’ or ‘energy efficiency gap’, as commonly referred in the literature (Brown and Gorgolewski 2014), is mostly around 30% and can reach up to 100% for more energy intensive buildings (Turner and Frankel 2008; Yudelson 2010). Apart from estimation errors, a major driver of the gap is diagnosed as people (i.e., occupants and building management) in the recent studies (Azar and Menassa, 2015). Studies show that energy consumption is significantly correlated with the occupant behaviour (Shrestha and Kulkarni, 2013) and if occupants understand the building and environment control systems, provided that the systems are designed to meet their requirements, they may contribute to lower building energy use (Day and Gunderson, 2015).

In office buildings, retrofitting do not only save energy and reduce operating costs but also contribute to the occupant’s health and comfort, resulting in decreased absenteeism and increased productivity (Ardente et al., 2011; Chidiac et al., 2011), and therefore increased return on investment (Korkmaz et al., 2010). Aktas and Ozorhon (2015) reports employee satisfaction is one of the prominent drivers why private companies choose to green their existing buildings. Similar to the energy efficiency gap, green office buildings may underperform in terms of occupant satisfaction and comfort. In the current practice retrofit design is generally based on code defined occupant comfort standards, however studies have shown weak and context-dependent correlations between standard-defined comfort ranges and occupant-reported comfort ranges (Wagner et al. 2007). Observations showed that a significant portion of the occupants remain dissatisfied with environmental conditions in offices after retrofits and dissatisfaction with physical conditions may lead to misuse of building systems, which worsen the overall occupant satisfaction and increase energy consumption (Jazizadeh et al., 2014).

To minimize the performance gap, in terms of both energy consumption and occupant satisfaction, occupant needs and expectations should be determined in detail before a retrofit process in an office building. There has been a vast amount of research on post occupancy evaluations to understand how actions performed by building occupants and facility managers affect energy consumption, and to what degree occupants are satisfied with specific physical conditions. However an empirically validated measure to determine the occupant satisfaction and requirements before an office building retrofit is missing in the literature. Therefore, significant potential for energy savings, occupant satisfaction and productivity gains, which could be realized through a more appropriate retrofit design, remains untapped.

The aim of this research is to develop an empirically validated and structured framework to measure occupant satisfaction and determine the needs and expectations of occupants in the pre-retrofit phase in office buildings. This paper explains the first phase of the research, which is the identification of the occupant satisfaction dimensions and indicators through a detailed literature survey. This research is expected to be a timely contribution to the green retrofit movement, which is expected to intensify even more in the coming years due to national and international legislations imposing more stringent standards and wide-spreading voluntary certification schemes embracing the green transformation of the existing building stock.

2. Previous Work on Occupant Satisfaction Measurement

Occupant satisfaction measurement is most widely adopted in Post Occupancy Evaluation (POE), which typically focuses on assessment of client satisfaction and functional fit with a specific space after occupation (Turpin-Brooks and Viccars, 2006). Presier (1995) defines POE as ‘a diagnostic tool and system which allows facility managers to identify and evaluate critical aspects of building performance systematically’. In comparison to the code defined standards and physical measurements, literature indicates a particular success of occupant feedback when evaluating performance metrics such as occupants’ thermal comfort, indoor air quality, space use and control by occupants, as no assumptions is made and all contextual influences are taken into account (Jazizadeh et al., 2014; Azar and Menassa, 2015). So, despite its general use in the facility management phase, it is beyond any doubt that occupant feedback can and should be used to complement physical measurements and code defined standards for the goal of identification of retrofit actions in office buildings.

Occupant satisfaction measurement tools may also be named as Indoor Environmental Surveys or Building Performance Evaluation Surveys in the literature. Table 1 presents an overview of the most widely used occupant satisfaction measurement tools and their comparative metrics. These tools may be classified into two sub-categories as (1) mostly academic in-depth studies that embrace a limited number of parameters to investigate a particular occupant satisfaction dimension, and (2) more comprehensive but unstructured surveys mostly used in the industry where dependencies among the constructs are not described.

*For references used in Table 1, please see Appendix 1.

A deeper analysis on the occupant satisfaction measurement tools reveals that most of these surveys and studies do not involve any information on the selection of indicators, or validation of the indicator constructs used. A few studies that present some form of validation of the constructs are limited to a particular occupant satisfaction dimension such as thermal comfort or lighting. Thus, analysis of the existing tools reveals the lack of an empirically validated and structured framework to measure occupant satisfaction with a holistic approach embracing different aspects of occupant comfort.

Developing a measurement framework requires a systematic approach to the identification of the dimensions and indicators of the phenomenon to be measured. Normative refinement analysis of occupant measurement tools listed in Table 1 revealed that dimensions and measures used in these tools are different but mostly complementary. Presented in the next section, as a first step in developing the occupant satisfaction measure, occupant satisfaction dimensions and indicators in the literature have been reviewed systematically and organized in a hierarchical structure to ensure content validity of the model.

The existing tools investigated also present important limitations making them ineffective in identifying the real causes of inefficient building operation since they do not aim to investigate the dissatisfaction sources, which would enable to determine the needs and expectations of occupants in the early stages of a new retrofit project. So, in addition to dimensions and indicators of occupant satisfaction, possible sources of dissatisfaction for each indicator were also determined from the literature and presented in the next section.

3. Occupant Satisfaction Dimensions and Indicators

In the quest to find the relevant dimensions and indicators of occupant satisfaction, a literature search was performed using the key terms ‘occupant satisfaction’, ‘post-occupancy evaluation’ and ‘workplace satisfaction’ in four major research databases, namely, Science Direct, Taylor and Francis, Emerald and ASCE. A total of 317 articles published between 2000-2015 were analysed with regards to indicators proposed to measure occupant satisfaction or sub-dimensions of occupant satisfaction such as thermal comfort, indoor air quality, spatial comfort. Post-occupancy evaluation tools and standards presented in the previous section were also used to identify dimensions and indicators of occupant satisfaction.

Frequency analysis and normative refinement methodology were adopted in merging indicators found. The detailed literature review procedure adopted ensures the content validity of the occupant satisfaction measurement model to be developed in the following stages of the research. As a first step in the development of the model, the dimensions and indicators identified from the literature were organized in a hierarchical structure. Table 2 presents these dimensions and indicators along with their sources.

*Table 2: Occupant satisfaction dimensions and indicators**

Occupant satisfaction was configured under eight dimensions and under each dimension, the related indicators were identified. For example, for thermal satisfaction dimension, indicators were determined as temperature, radiant temperature, relative humidity and temperature shift. In total, twenty nine indicators were identified. It should be noted that while determining the indicators, the goal was to define the unobservable facets of occupant satisfaction via indicators that can be assessed by the users. Therefore, the indicators which require data collection at buildings by using devices (e.g., CO_2 emmision) are not included in the scope of this study. In addition, possible sources of dissatisfaction for each indicator were determined from the literature. For example, for temperature sources of dissatisfaction were identified as 'too cold', 'too hot' and 'unstable'. These dissatisfaction sources are intended to be used for determining the needs of the occupants and therefore priority areas to work on in the pre-retrofit phase.

4. Conclusions

Occupants can be a useful and inexpensive source of information in identification of the retrofit actions required in office buildings. In this paper post-occupancy evaluation tools and standards as well as academic studies were analysed in order to understand the approach, dimensions and indicators used to measure occupant satisfaction. According to Turpin-Brooks and Viccars (2006), an effective occupant satisfaction measurement tool needs to give comparable results, be reliable and address all factors that relate to the needs, activities and goals of the people using the specific type of the building considered. Existing occupant satisfaction measurement tools however, lack an empirically validated construct and a holistic approach embracing different aspects of occupant comfort in office buildings. As a first step in developing the occupant satisfaction measure, occupant satisfaction dimensions and indicators in the literature have been reviewed systematically and organized in a hierarchical structure to ensure content validity of the model. The proposed occupant satisfaction construct is intended to be empirically validated with an appropriate method in the following stages of the research, also determining the possible interactions with comfort conditions, occupant health and productivity. This study is expected to help identify and solve existing problems that hinders occupant satisfaction and guide the design of retrofits in the office buildings to maximize building performance and users' needs.

Abstract

A good student experience at the university is important for both the student and the institution as it has been shown to improve student progression rate and improve the through-put of students. The quality of the academic experience enjoyed by students is determined to a large extent by the teaching and learning philosophy employed. For education in construction related studies, the general teaching and learning philosophy used is the traditional lecture approach which is strongly instructive in nature. However, for the Architecture programme, the studio approach, which exhibits attributes of a constructivist approach, is the *modus operandi* philosophy of teaching and learning. Notwithstanding that the Architecture studio approach is coupled with the instructive lecture approach, differences in student learning experiences are expected to prevail between students of Architecture compared to students of other construction related programmes such as Quantity Surveying and Construction Management due to the differences in teaching and learning philosophies. This study therefore sought to determine if there are in fact any differences in learning experiences offered by the Architecture programme compared with learning experiences in Quantity Surveying and Construction Management programmes due to the studio approach to Architecture education. To achieve this, a self-administered questionnaire survey was conducted with students at three South African universities offering Architecture, Construction Management and Quantity Surveying programmes. A total of 194 registered students were surveyed. Using the Kruskal Wallis test and the Mann-Whitney U test, significant differences were found in some experiences between Architecture and the combination of Construction Management and Quantity Surveying and also in individual associations between Architecture and Construction Management and between Architecture and Quantity Surveying. However, as expected no significant association was found in any of the measured constructs between Quantity Surveying and Construction Management. The results therefore suggest that there are significant differences in learning experiences between Architecture and other construction programmes due to the studio approach to Architecture education. However, the differences are moderated by the fact that Architecture still relies on a significant amount of instructive lectures alongside the studio approach.

Keywords: Student experience, Learning experiences, constructivist, instructive, Studio learning, construction programmes

1. Introduction

The quality of the student academic experience during university education is cardinal to the success of both the student and the institution and is critical for producing quality graduates (Morgan 2016). Student experience refers to all the aspects of student life including academic, social, welfare and support (Ibid). The academic student experience is significantly determined by the general philosophy underpinning the delivery of the education. Generally, the philosophy of education delivery can be broadly divided into the two groups of the traditional instructive approach and the more contemporary constructivist or student centred approach. Construction education has largely been delivered through the traditional instructive approach with the exception of architecture, which, through the use of the studio approach, exhibits strong attributes of a constructivist approach.

A constructivist learning approach is distinctive from the traditional instructive approach in a number of ways. It is structured so that the learning is centred on the student by having the student actively participating in the learning. The approach is also based on a two-way communication system between the learner and the instructor with both parties sharing knowledge and experiences to promote active construction of knowledge by the learner. The traditional instructivist teaching approach on the other hand is characterised by a passive and rather uninvolved learner receiving knowledge in a one-way transmission process. Some educators have described the instructivist approach as being unsuited to learning and suggested that it perpetuates the production of graduates who are ill prepared for professional practice (Jungst, et al. 2003).

Notwithstanding that architecture uses the constructivist studio based learning, it also incorporates a fairly significant amount of instructive lectures as well. However, the equally significant use of the studio learning is very likely to significantly impact on the academic experience of the students. Therefore, compared to the rest of the construction programmes which do not make any significant use of the studio based learning, differences in the academic experience of architecture students are very likely to exist. This study therefore investigates the academic experiences of students undertaking construction studies and posits that there are significant differences in academic experiences of students of architecture and the rest of the students pursuing construction studies.

2. Studio-based Learning

Studio-based learning (SBL) is an instruction approach which is centred on the collaborative application of several module contents and skills in a project the solution of which is presented for peer review and revised based on peer review (Vest, et al. 2011). It has received widespread application on architectural education practice whereby, while different design modules are taught separately, students are expected to demonstrate their understanding of these different distinct modules by applying their understanding to a design problem called a studio project (Hundhausen and Brown 2008; Nasir, et al. 2011; Vest, et al. 2011). In the SBL approach, students must construct a solution to a complex problem, present the solution to peers, participate in a critique ('crit') of the solution to peers and respond to criticism by revision or rebuttal (Hundhausen and Brown 2008). The lecturer plays the role of an instructor who both critiques and provides appropriate guidance to the student (Nasir, et al. 2011). The SBL approach is so central to the development of architects that no architecture programme is taught without it. Therefore, the results of the SBL approach to architecture education can be seen in its strict application of the philosophy. Owing to its remarkable success with architecture, other fields of learning have also embraced SBL. For example, Hundhausen and Brown (2008) applied the SBL approach to a computer science class where the students were tasked with developing the solution of an algorithm problem and reported evidence of the efficacy of the studio-based learning approach in a setting other than architecture education.

The studio approach in architecture education is based on the '*atelier'* system which has its history in the prestigious Ecole des Beaux Arts in Paris (Fricker and Fricker 2010; Lackney 1999; Oh, et al. 2012; Simon 1996; Van-Alen-Institute nd). The *'atelier'* system is an educational approach whereby apprentices in fine arts and architecture were trained by experienced 'masters' in an *atelier,* which is the French word for 'workshop' or 'studio' (Simon 1996). The Ecole des Beaux Arts, which is perhaps the oldest formal learning institution offering education in fine arts and architecture, used this approach since its inception in 1648 (Fricker and Fricker 2010). The approach was borrowed from the training of apprentices before formal education which involved experienced 'masters' taking on a small number of apprentices in their *ateliers* until the apprentices had mastered the art (Simon 1996). The *atelier* system lent itself very well to the training of architects because of the practical nature of art rather than science of architecture, and subsequently the need for apprentice architects to practice their craft in an architectural studio. The system worked so well that in fact as professional education shifted from the *atelier* to colleges and universities, and even as architecture education spread from Europe to America, and to the rest of the world, the studio approach became the *modus operandi* in architecture education (Lackney 1999; Van-Alen-Institute nd).

The student centred approach inherent in SBL is very similar to approaches found under constructivist learning models. Loyens et al. (2009) suggested four characteristics of a constructivist learning approach, namely, knowledge construction, cooperative learning, metacognition and authentic learning tasks. Knowledge construction in a SBL takes the form of the student piecing together knowledge from different modules and applying it to a novel problem thereby constructing new knowledge. The presentation of the suggested solution to peers and the instructors allowing for feedback through rebuttal or revision permits cooperative learning to happen. Metacognition, is built into the process by allowing students time to carefully reflecting on the responses provided by the peers and the instructor and subsequently revise their solutions after a 'crit' session. The studio project itself is normally the development of a solution to an authentic task. While this analogy between SBL and a constructivist lesson are drawn based on only one description of a constructivist lesson, even with other differently named characteristics of a constructivist lesson, the central tenets among all constructivist approaches are the same and so the analogy remains valid. Therefore, SBL very closely resembles a constructivist lesson.

3. Constructivist Teaching Approach

As illustrated in Figure 2, the constructivist teaching model allows a creative process to take place during the interaction between the different parties via the learning situation designed by the teacher. The constructivist teaching model facilitates students' creation of their own knowledge, as they are allowed to think more over the problems together and generate original ideas. So constructivist teaching is characterised by students' active participation in class when they construct knowledge. The focus shifts from the teacher transferring knowledge, to students constructing knowledge by themselves; that is, from teacher-centredness to student-centredness in a multi-directional manner (Yuen and Hau, 2006). Interchanges between student and instructor as well as between student and student are permitted and encouraged. Constructivist teaching by nature is empowering, because teachers assist students in developing new insights and making connections with previous knowledge while leaving the discovery of the knowledge to the students. This way, students are able to develop their own understanding of the subject matter based on previous knowledge and can correct any misconceptions they may have had. By explaining their ideas to other students, they are active participants in their own education and are able to come to a clearer understanding of the concepts being learnt (Ibid).

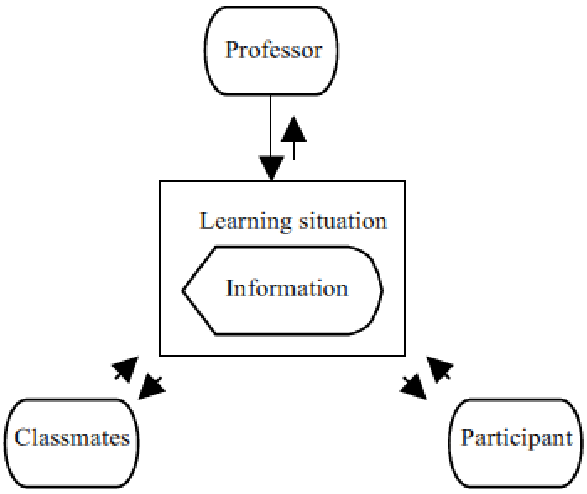

Figure 1: The constructivist teaching model as adapted from Yuen & Hau, 2006

4. Instructivist Teaching Approach

The traditional lecture approach to learning differs significantly from both the constructivist approach and SBL in that the traditional approach is strongly instructivist in nature. Instructivist teaching is most commonly understood as being a traditional, direct instruction, teacher/instructor-centred approach whereby students in the classroom are passively receiving information and knowledge. Put very simply, direct instruction means teachers/instructors telling students the things they need to know (Nasir, et al. 2011). The traditional classroom can sometimes resemble a one-person show with a captive but largely uninvolved and passive audience. This teaching approach can be seen graphically in the Yuen and Hau (2006) model shown in figure 2. The model illustrates how the traditional approach is instructivist in nature with a one-directional flow of information. Students are expected to passively receive the knowledge from the teacher with very little engagement with the lesson. In this approach, the teacher seeks to transfer thoughts and meanings to passive students, leaving little room for student-initiated questions, independent thought, or interaction among students as well as between students and the teacher. This teacher-centred method of teaching also assumes that all students have the same level of background knowledge in the subject matter and are able to absorb the material at the same pace (Lord, 1999).

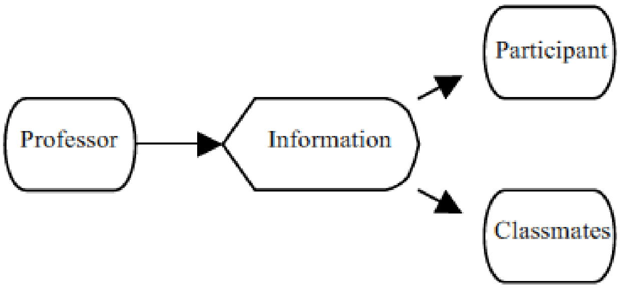

Figure 2: The teacher-centred teaching model as adapted from Yuen & Hau, 2006

5. Instructivist and Constructivist student experiences

Arising from the differences inherent in the teaching approaches of the constructivist and the instructivist models, differences in student experiences abound. In a constructivist academic environment, students experience a learner-centred approach rather than the teacher one-directionally communicating defined bodies of knowledge (Kember 1997). Active learning occurs multi-directionally with students engaged in discussing, questioning and solving problems and taking more responsibility for their own learning (Gibbs and Unit 1988; Prince and Felder 2006). In the instructivist teaching methodology, students are passive learners, receiving information without question. In a constructivist model, students actively construct their own meaning of knowledge (Bruner 1990) while in the instructivist model, they merely receive information.

The constructivist characteristics intrinsic in the SBL approach in the architectural design studio module therefore carries some, if not all, the differences in student learning experiences highlighted. Based on the description of the studio approach, four distinct differences in studio experiences with the traditional instructivist approach would be expected. Firstly, the role which the lecturer in an architectural design studio lesson plays changes from source of knowledge to critique and guidance instructor (Singer and Moscovici, 2007). Secondly, the nature of problems administered to students in an architectural design studio are complex with no single accepted solution and require students to combine knowledge from several modules to synthesize the solution. Thirdly, the students are engaged more actively with their lessons because of the 'crit' sessions which provide very effective formative assessment and the opportunity for the students to explain their thinking and therefore more effectively demonstrate their understanding of key design concepts (Hundhausen and Brown, 2004). Finally, the architecture design studio is different from the traditional lecture approach in that the mode of lesson delivery is strongly student centred as opposed to the strongly teacher centred approach in the traditional lecture system. These differences and others can be seen in Table 1.

Table 1: Comparison of Student Experience

Construct	**Students Experience**	
	Constructivist	**Instructivist**
Role, commitment and involvement of instructor	• Critique • Facilitating • Guiding	• Directing • Instructing
Nature of problems	• Complex • Generation of ideas	• Theoretical
Student engagement	• Active • Knowledge sharing • Knowledge creation/construction	• Passive • Uninvolved • Knowledge acceptance
Mode of delivery/transmission	• Group work • Two-way transmission	• Individual • One-way transmission

6. Research Design

Research was conducted to establish whether there are any differences in learning experiences between architectural students and the rest of the students engaged in construction studies due to the conceptual differences in instruction approaches used in the design studio of the architecture programme and the instructive approach used for the rest of the construction programmes. The research was designed to measure the perceptions of students about their educational experiences. The design of any research study is concerned with the plan to assemble suitable data for investigating and testing the research hypotheses (Welman and Kruger, 2001). The methods used to gather information depend on the type of data and the problem to be researched (Leedy and Ormrod, 2001). For this study, a self-administered questionnaire survey was conducted with students at three South African universities offering construction management, quantity surveying and architecture programmes. The student survey forms part of a larger national study that evaluates the experiences of students in their academic construction programs. The data were analysed using SPSS version 22.

The population of interest was all South African universities offering construction related programmes. However, due to resource limitations, convenient quota sampling was used to select a sample of three universities. Time and cost conveniences were the main criterion used for selecting the quotas. All students in the selected universities were then targeted for inclusion in the sample.

Four constructs measuring aspects of learning experiences identified from literature as being likely to exhibit differences between architecture students and the rest of the students pursuing construction studies were investigated. The four constructs are “Role, Commitment and Involvement of Instructors”, “Nature of Problems”, “Student Engagement” and “Mode of Delivery/Instruction”. Each construct had items ranging from 8 to 12 and responses were measured using a five-point Likert scale with 1 = “Strongly Disagree,” 2 = “Disagree,” 3 =“Neutral,” 4 = “Agree” and 5 = “Strongly Agree”.

The questionnaires were administered to all students present at the time of sampling in each programme at the selected universities. The sampling was done at different days for each of the universities. A total sample of 194 registered full-time students from all three universities was obtained.

7. Discussion and findings

The convenience sample comprised of 194 full-time registered students at three universities in South Africa, made up of 88 (45%) male and 105 (54%) female students with one student not responding. Students were registered in all years of study as follows:

- Architecture – 81 (42%);
- Construction Management – 41 (21%); and
- Quantity Surveying – 72 (37%).

The degree of internal consistency or Cronbach Alpha scores for the scales used for the four student experience constructs is shown in Table 2. All the constructs were found to have statistically high internal reliability, namely Cronbach Alpha values >0.700. The scores ranged from 0.902 (role, commitment and involvement of instructors) to 0.799 (nature of problems). There is therefore between 90.20% and 79.90% probability that the constructs each measure a single underlying concept with an error of at most 5%. The scales used to measure the four selected areas of student experiences are therefore reliable in their measure of the constructs.

Table 2: Reliability Statistics

Scale	Cronbach's Alpha	No of Items
Role, Commitment and Involvement of Instructors	0.902	14
Nature of Problems	0.799	8
Student Engagement and Empowerment	0.849	11
Mode of Delivery/Transmission	0.869	8

Descriptive statistics for the four constructs have mean scores ranging from 3.59 to 4.05 as shown in Table 3.

Table 3: Descriptive Statistics for Aggregate Scores

	Role, commitment and involvement of instructors	Nature of problems	Student Engagement and Empowerment	Mode of delivery/ transmission
N	194	193	193	194
Mean	3.588	3.863	3.833	3.772
Std.	0.624	0.570	0.586	0.641

The data were tested for relationships. However, before any tests of association were performed, a test of normality was performed to establish the statistical distribution of the data and therefore establish the appropriate statistical tests to use between parametric and non-parametric tests. Table 4 presents the results of the Shapiro-Wilk test of normality which tests the null hypothesis that the data are drawn from a population which follows a normal distribution. The significance values less than 0.05 suggest that there is no evidence to support the null hypothesis and so it can be concluded that the data is not normally distributed and therefore only non-parametric tests should be used.

Table 4: Test of Normality

	Shapiro-Wilk		
	Statistic	df	Sig.
Role, Commitment and involvement of instructors	0.982	193	0.013
Nature of Problems	0.971	193	0.000
Student Engagement and Empowerment	0.976	193	0.002
Mode of Delivery/transmission	0.977	193	0.003

To establish whether there were significant associations between the constructs measuring student experience and the different disciplines with the different instruction approaches, the non-parametric Kruskal-Wallis test was used. This test typically measures whether or not there are any differences in three or more sample means (Chan and Walmsley, 1997). It tests the null hypothesis that the samples are drawn from the same population.

Test statistics for the constructs "Role, Commitment and Involvement of Instructors" and "Mode of Delivery/transmission" are less than 0.05 as can be seen in Table 5. Therefore, for these constructs, the null hypothesis is rejected and it can be concluded that there are distinct differences in experiences among the three disciplines when it comes to these constructs. The three disciplines exhibit no significant differences in their perceptions of "Nature of Problems" and "Student Engagement and Empowerment"

Table 5: Association among all Disciplines

	Role, Commitment and Involvement of Instructors	Nature of Problems	Student Engagement and Empowerment	Mode of Delivery/transmis sion
Chi-Square	12.153	5.878	2.540	9.208
Df	2	2	2	2
Asymp. Sig.	0.002	0.053	0.281	0.010

a. Kruskal Wallis Test

b. Grouping Variable: Discipline

In order to establish whether the observed differences in the experiences of the respondents on "Role, Commitment and Involvement of Instructors" and "Mode of Delivery/transmission" can be attributed to the architectural students, individual associations between architectural students and construction management students and between architectural students and quantity surveying students and also between construction management and quantity surveying students were performed. The Mann-Whitney U test, which is a non-parametric test which compares two sample means to establish whether the means are equal or not. It tests the null hypothesis that the two samples are drawn from the sample population.

Table 6: Association between Architecture and Construction Management

	Role, Commitment and Involvement of Instructors	Nature of Problems	Student Engagement and Empowerment	Mode of Delivery/trans mission
Mann-Whitney U	1317.500	1233.000	1556.500	1173.000
Wilcoxon W	4638.500	2094.000	4796.500	4494.000
Z	-1.861	-2.235	-.458	-2.648
Asymp. Sig. (2-tailed)	0.063	0.025	0.647	0.008

a. Grouping Variable: Discipline

Table 6 shows that the experiences of students in Architecture are significantly different from those of Construction Management students in the constructs of "Nature of Problems (0.025) and "Mode of Delivery/Instruction" (0.008) since these are not coming from the same population. Also, Table 7 shows that when architecture students and quantity Surveying students are compared, significant differences in student experiences are found in "Role, Commitment and Involvement of Instructors" (0.001) and "Mode of Delivery/Transmission" (0.015).

Table 7: Association between Architecture and Quantity Surveying

	Role, Commitment and Involvement of Instructors	Nature of Problems	Student Engagement and Empowerment	Mode of Delivery/trans mission
Mann-Whitney U	1985.500	2418.000	2447.500	2254.500
Wilcoxon W	5306.500	5046.000	5687.500	5575.500
Z	-3.404	-1.710	-1.598	-2.422
Asymp. Sig. (2-tailed)	0.001	0.087	0.110	0.015

a. Grouping Variable: Discipline

Table 8: Association between Construction Management and Quantity Surveying

	Role, Commitment and Involvement of Instructors	Nature of Problems	Student Engagement and Empowerment	Mode of Delivery/trans mission
Mann-Whitney U	1277.000	1332.500	1339.000	1391.500
Wilcoxon W	2138.000	2193.500	2200.000	4019.500
Z	-1.190	-0.860	-0.820	-0.506
Asymp. Sig. (2-tailed)	0.234	0.390	0.412	0.613

a. Grouping Variable: Discipline

From Table 8, it is evident that there are no significant associations between the experiences of students registered for construction management and quantity surveying. This finding is not unexpected given that the mode of instruction is the same for both disciplines and firmly establishes the observed significant differences in student experiences originates from Architecture.

A correlation analysis revealed no significant correlations in student experiences when all the disciplines were grouped together. However, when Architecture was correlated individually with Quantity Surveying, significant correlations were found in the constructs of "Role, Commitment and Involvement of Instructor" ($r = 0.276$, $p = 0.001$) and "Mode and Delivery/Transmission" ($r = 0.196$, $p = 0.015$) as shown in Table 9.

Table 9: Architecture and Quantity Surveying

Role, Commitment and Involvement of Instructors	Correlation Coefficient	0.276**
	Sig. (2-tailed)	0.001
	N	153
Nature of Problems	Correlation Coefficient	- 0.139
	Sig. (2-tailed)	0.087

When Architecture was correlated individually with Construction Management as shown in Table 10, the associated student experiences with coefficients ranged from 0.204 to -0.241 with significant association in "nature of Problems" ($r = 0.204$, $p = 0.025$) and in "Mode of Delivery/Instruction" ($r = -0.241$, $p = 0.008$). No significant correlations were found between Quantity Surveying and Construction Management.

8. Conclusions

There are significant differences in learning experiences between students of Architecture and students of other construction related disciplines. Differences in students' learning experiences were found in comparisons of Architecture with Quantity Surveying and Architecture with Construction Management in two of the four constructs studied. No significant differences were found between Quantity Surveying and Construction Management. The significant differences found in associations with Architecture coupled with the absence of significant differences found in associations without Architecture suggest that student learning experiences in Architecture differ significantly from the rest of construction programmes.

While individual modules taught in Architecture are delivered through the traditional instructive approach similar to the rest of the construction programmes, Architecture differs from the rest of the programmes in that it is further characterised by the studio approach which is much more student centred and therefore exhibits attributes of constructivism. Therefore the difference in learning experiences found in associations with Architect and absent in associations without Architecture can be attributed to the studio nature of the learning approach used in Architecture programmes since it is the only variable of difference between Architecture and the other construction programmes. The differences found in the constructs of "Role, Commitment and Involvement of Instructors" and "Mode of delivery/Instruction" further support the notion that the studio approach is responsible for the differences since it the module where the role of the instructor differs from the role played in other modules. Also, studio is the only module where the mode of instruction is different.

Differences were expected to be larger and to be present in all four constructs studied. The absence of differences in some of constructs may be attributed firstly to the fact that even if architecture relies on the studio approach, it still has modules taught through the instructive approach and therefore the effect of the studio approach is moderated. Secondly, students may have given their opinions in some instances rather than their experiences. An element of reporting perceptions rather than experiences may have crept into the responses particularly in the responses from the construction management and quantity surveying students due to how the programmes are in fact taught in the South African universities. Therefore, in this kind of survey, one needs to be extremely cautious and provide very clear instructions to the participants to avoid misunderstanding of what is expected from them.

While this study has established differences in learning experiences between Architecture and Quantity Surveying and Construction Management in some learning experiences, it remains to be established whether the differences are positive towards Architecture or otherwise. This is worth establishing so that the viability of a studio approach to other construction programmes can be investigated.

Abstract

The purpose of this paper is to develop an analytical model for further verification of design and engineering as processes of learning. Such a model should in particular be able to uncover that design projects mature progressively through interactive processes with strong reciprocal and sequential dependencies. We assume that the linear waterfall style of project management for design and engineering is not adequate for coping with the nature of design and engineering. Following the verifications, the next step in this research is to develop a model for improved design management.

The paper addresses the nature of design and engineering and learning theory, and contributes to an improved understanding of the phenomena in question.

Keywords: design, learning, analytical model

1. Introduction

Project planning and engineering are activities that aim to create a foundation for some kind of artefact, e.g. a building with functionality defined by the customer, a bridge or a ship. Kalay (2004) refers to design as a cyclical relationship between two paradigms; design as problem solving, where the designer attempts to produce solutions to ill-defined problems, and design as puzzle making, where design is seen as a process of discovery, where given parts are synthesized into a new and unique whole. The design process, particularly in its early stages, can be characterized by a progressively clearer understanding of the scope, reciprocal interdependencies (Thompson 1967, Kalsaas and Sacks 2011) between different disciplines and subjects, and iterative processes and loops. Iterations can be positive or negative (Ballard 2000).

Several authors characterize Last Planner System (LPS) as a system of learning (e.g. Ballard, 2000; Rooke, 2005; Koskela et al., 2010), which is tied in particular to the high level of focus on involvement, and the mechanisms that are related to the evaluation of completed work plans, and root-cause analysis (continuous improvement). However, it seems like there has been a lack of contributions to uncover, in depth, why this is the case. Some exceptions are Kalsaas (2012) and Skinnarland and Yndesdal (2012). Kalsaas analyses LPS through a learning perspective, which is based, in particular, on Kolb`s (1984) experiential learning theory and Illeris` (2009) model of workplace learning. Skinnarland and Yndesdal (2012) focus on LPS as a system of knowledge development. The authors ties their theories to collective learning processes, inter alia, Nonaka and Takeuchi`s (1995) well known SECI model.

In the context of this paper, the authors are trying to understand the design process as a learning activity. The relevance is tied to the ability to gain a greater theoretical notion of design as a learning phenomenon, which will create an understanding that can be used to improve design management. For instance by providing a framework that utilizes the learning process in the most effective manner. The paper is structured as follows: at first we investigate the architectural design process, then we look at a selection of learning concepts. Finally, we discuss an analytical model for future research.

2. The architectural design process

Throughout the evolution of design practice, there have been countless attempts to tackle the challenge of understanding, mastering and explaining the processes behind our built environment. The first generation of design methodologists' focus on the design process as something sequential and linear in the 1960s, has long been challenged (Lundequist, 1992). The understanding of the architectural design process as a complex universe of predictable and unpredictable interactions, interrelations and interdependencies between actors and their actions, relates to observations of the practice of architectural design made by researchers such as Cuff (1991), Kalay (2004), Lawson (2006) and Schön (1991).

According to Cuff (1991), the design process is a social construction, where buildings are collectively conceived. Kalay (2004) refers, as previously described, to design as a cyclical relationship between problem solving and puzzle making. Lawson (2006) describes the design process as "a negotiation between the problem and solution through the three activities of analysis, synthesis and evaluation," and challenges the comprehension of the design process as a sequence of activities. He sees the design process to be a simultaneous learning about the nature of the problem and the range of the possible solutions. In the beginning of the design process, the architect, the engineer or the client do not know exactly how the building will look like, what are the problems to come or even what are the requirements to be fulfilled. Schön (1991) characterizes design practice as a reflective dialogue between the designer and the design situation and he emphasizes the crucial role of tacit knowledge. This kind of "feeling of" can be expressed, for instance, by experience-based, intuitive and unconscious habits and actions. This knowledge embodied by the practitioners involved in architectural design is crucial, but hard to grasp and unlock.

The features of the architectural design process described above are closely related to cognitive processes and design thinking. Some features are, however, also given by regulating external factors. Examples of these are (highly simplified):

- The delivery of design information and project material to the stakeholders (client, the building authorities and contractors) are regulated in phases. Each phase presents a higher level of detail and information depth, and each has to be approved by the stakeholders before moving on to the next phase.
- The time and performance related definitions of these phases are mostly specified in the project contracts. These might again be regulated by guidelines or regulatory demands on national level.
- The architectural design process is situated between the statement of the brief (more or less defined) and the start of the building production on the construction site. In practice, limited time resources, tough project budgets and the contractual models might often call for an overlap of the phases (e.g. starting up the work on the construction site before the design phase is completed).

Bearing the two above-mentioned groups of features in mind, the practitioners involved in the architectural design process must deal with an interplay between highly iterative, unpredictable and non-linear activities on the one hand, and regulated and linear activities on the other. Moum (2009) uses the metaphors of "baking bread" and "playing jazz" to highlight and simplify the different character of these features of the architectural design process. Baking bread could be seen as a linear, predictable, explicit and measurable process - based on for instance repetition and routine. This can be related to the activities described above, which are central in order to drive the processes forward due to the agreed time and cost. Playing jazz is on the contrary a rather improvised, intuitive and tacit process leading to a unique performance, based on "the feeling of", on talent, practice and experiences. This process might be compared with the hard-to-grasp elements of the architectural design practice described in the beginning of this section. This "something" going on in the head of the designers, is also a magical "something" resulting in the unique and great architectural solutions and buildings. The "baking bread" and "playing jazz" metaphors are representing co-existent processes in the architectural design practice. The interplay and balance between these are crucial for what actually gets built.

3. Concepts of learning

3.1 Experience-based learning theory

Kolb (1984) emphasises that learning is a process rather than a result. He furthermore claims that knowledge is a transformation process continuously created and re-created, it is not an independent entity that can be acquired or transmitted. Knowledge creation occurs at all levels, from the most advanced forms of scientific research to the child's discovery that being stung by a wasp is a painful experience that is best avoided in the future. "Knowledge" is the outcome of a transaction between social knowledge and personal knowledge. Social knowledge (Dewey, 1938) is the civilised objective accumulation of previous human cultural experiences, whereas personal knowledge is the accumulation of the individual person's subjective life experiences. Knowledge results, then, from the transaction between these objective and subjective experiences in a process called learning. Hence, according to Kolb, to understand knowledge, we must understand the psychology of the learning process; and to understand learning, we must understand the epistemology – the origins, nature, methods, and limits – of knowledge. Kolb draws heavily on Piaget (1970a) when he emphasises the need for epistemological understanding.

Furthermore, Kolb builds above all on Lewin (1951), Dewey (1910, 1934, 1938, 1958) and Piaget (151, 1968, 1970a, 1970b, 1971, 1978) when developing this well-known model for experiential learning. In this model, the process and structure of learning are depicted as a four-stage cycle involving four adaptive learning modes. These evolve from 1) concrete experience; 2) reflective observation; 3) abstract conceptualisation; and 4) active experimentation. This learning cycle can be understood as a continuous spiral where the different cycles of adaptive learning are repeated in order to allow for further learning. An onion can be used as a metaphor for this process, each layer representing a level of knowledge. Combining the four learning modes, Kolb divides them into two dimensions, where they represent pairs of dialectically opposed adaptive orientations, namely; 1) concrete experience versus abstract conceptualisation; and 2) active experimentation versus reflective observation. The abstract - concrete dialectic is one of "prehension". Prehension is a concept invented by Kolb to describe the representation of two different and opposed processes of grasping or taking hold of experience in the world. This either by relying on conceptual interpretation and symbolic representation, a process described by Kolb as "comprehension" – or by relying on the tangible, felt qualities of immediate experience, which he describes as "apprehension". The active-reflective dialectic is seen as one of transmission, representing two opposed ways of transforming what has been grasped through the prehension of experience. Either through internal reflection, a process Kolb describes as "intention" – or through active external manipulation of the external world, described as "extension". There is thus a clear "division of labour" between these two dimensions of learning; namely that of capturing or grasping experience, and of ensuring that what is grasped, is transported to the level where it is translated into internal understanding and/or external action.

3.2 Workplace learning

Whereas Kolb's model is primarily a model for individual learning processes, Illeris' (2009) model, expanding on the works of Jørgensen and Warring (2002) and Botterup (2000), helps integrate an understanding of individual learning into an understanding of learning in working life. For workplace learning, Jørgensen and Warring (2002) have developed a model based on the concepts of learning environment and learning progress, where learning is seen as taking place in the intersection between the learning environment of the workplace and the learning progress of the employees. A distinction is made between the technical-organisational learning environment and the social learning environment. The technical-organisational aspect is constituted by the material conditions tied to technology and to the way the work is organised, which may, for example, facilitate or limit work variation, and thus impact on the possibilities for learning. The work community and social interaction constitute the social learning environment. Learning progress is linked to each employee's background and stage of life, as well as to his or her capacity to be open to and benefit from learning. Learning takes place in a dynamic interaction between the learning environment and the individual's learning progress.

Illeris (2009) divides the technical-organisational learning environment into six categories: 1) division of tasks/work; 2) work content; 3) scope for decision-making; 4) scope for using one's qualifications; 5) scope for social interaction; and, 6) work strain. A rigid division of work can undermine the individual's perception of the work as meaningful (Taylorism). Work content is linked to the work's social significance and to its significance for the individual (learning progress). The scope for deciding over one's own work is connected to the style of leadership (dialogue versus orders from above) and to the organisational structure (flat structure and decentralised decisions versus hierarchical, bureaucratic structure). Illeris points out that the opposing ideas and interests, which emerge in the encounter between different trades or professions, can create fertile learning environments. They can, however, also help consolidate mutual myths and images that place the other party in the role of being an opponent. Technological conditions are very important for the scope for social interaction and for the social learning environment. Work performance pressures (speed and intensity) can hamper learning because they interfere with the time or physiological/mental energy needed in order for learning, development, experimentation and trying out of new ideas to take place.

Based on Botterup (2000), this part of the model can be expanded to include "work practice". Work practice is connected to society in the interface between the technical-organisational environment and the social learning environment – which is now expanded and described as "the social and cultural learning environment". The practice concept contains what actually takes place "in practice", but it also includes practice as a constituting expression of human consciousness and learning.

In the general learning model, which is individually oriented, Illeris (2009) distinguishes between three dimensions: the cognitive dimension; the psychodynamic dimension; and the surroundings/society. The acquisition process of learning takes place between the cognitive and the psychodynamic dimensions, which in their turn interact with society; whereas work identity is found in the tension between the cognitive and emotional dimensions. The cognitive dimension includes aspects of content and reason. It is linked to what Habermas (1984, 1987) describes as "the system". The psychodynamic dimension covers motivational and emotional aspects, and is linked to Habermas's "lifeworld". It is society that provides the conditions for learning. The lifeworld is tied to communicative rationality, and the system to instrumental rationality, and the two are strongly intertwined. Lundvall (1992) relates "instrumental" rationality to the expected outcome of interaction (cause-effect); and "communicative" rationality to intuition, worldviews and other factors related to communication. Habermas's theoretical contribution is often used in the innovation literature; see e.g. Moodysson (2007) and Kalsaas (2011).

Illeris distinguishes between different forms of learning in the cognitive dimension. He describes "assimilative" learning as a general form of learning: it is used in everyday life in the encounter with new impressions and impulses. This is also the most common form of learning in schools, as the students' knowledge is gradually built up over time. "Accommodative" learning is a more demanding form of learning, as it transcends boundaries. In this kind of learning, we cannot immediately understand or relate to what is happening. It requires that existing understandings are overcome or broken down, which in turn requires creative efforts to restructure what is already known, through reflection. This is denoted “relearning” in Kolb’s work. So-called “aha experiences” and a perception that “the pieces have fallen into place” occur in relation to this form of learning. Accommodative learning is crucial in any attempt at introducing improved work practises. “Transformative” learning is the most demanding form of learning examined by Illeris. We may encounter this type of learning if we lose our job and have to retrain in order to get a new one, which often means that we have to develop a new worldview or a new basic outlook. This can be perceived as a life crisis on the personal level.

The psychodynamic dimension of learning, with its emotional, intentional and motivational patterns, is influenced by the cognitive dimension in the shape of our knowledge and skills. For example, so-called “bad chemistry” between individuals can drastically hamper our ability to learn. However, if we gain better insight into the work of those we do not initially feel sympathetic towards, such emotions may change. The reasons for defensiveness and resistance to learning are found in the emotional dimension. Illeris sees the factor of “defending identity” – which is one of several mental defence mechanisms – as crucial in this context. In our working lives we often establish an identity tied to something we master well, and which others also consider us as proficient at. For example, someone may be good at using an advanced control system, PLC controlling, programming, and so on. Strong work identities can easily lead to active resistance to any change, which might threaten these identities – such as change that involves an accommodative learning process. According to Illeris, the general tendency for adults is that the more demanding and complicated the learning requirements, the greater the psychodynamic barriers in the shape of defensiveness or resistance. Levin and Klev (2001) point out that learning is often prevented because we wish to avoid situations in which individuals might lose face. This is also a central concern in Argyris’s (1990) works. This phenomenon can be linked to the psychodynamic dimension.

The best conditions for workplace learning are found in the area where work practice and work identity overlap. It is possible to imagine that if there is no such overlap, individuals might try to modify their work practices in such a way that they become aligned with their work identity, or they might resign and look for work with a different employer.

3.3 Learning loops and learning cycles

Ashby (1960) and Argyris and Schön (1996) distinguish between single-loop and double-loop learning. Single-loop learning can be conceptualised as “Doing Better”, and double-loop learning as “Doing Differently”. It is part of the nature of this difference between double and single loop learning that beginning to do things in a different way is more demanding than pursuing the already established strategy, but with a few adjustments, in terms of the learning involved (in other words, assimilative versus accommodative learning). Expanding on Ashby (1960), Argyris and Schön (1996) argue that for a company, “doing differently” might require external resources to be brought in to help with the improvement work. Thus, greater competence on grasping via comprehension can be built through action research approaches where academics and researchers cooperate with the company. This relates to the traits considered by March (1999; see below) as limiting the value of experiential learning.

Rooke (2005) relates Kolb's (1984) experiential learning cycle to Deming's Quality Cycle (Deming, 1986), also widely known as "Plan-Do-Check-Act". "Plan" relates to abstract conceptualisation; "Do" to active experimentation; "Check" to concrete experience; and "Act" to reflective observations. Deming's quality circle, which draws on his joint work with Shewhart from 1939, is, in all its simplicity, widely applied in lean implementations and popular among consultants in the field. However, unlike Kolb's work (1984), the quality circle does not offer any conceptualisation of learning as such. Rather, it is assumed that learning is likely to take place along the course of the Plan-Do-Check-Act cycle.

3.4 The limitations of experiential learning

According to March (1999), learning from experience does not produce perfect results by itself. It has its limitations. Firstly, experiential learning tends to exaggerate the importance of actual events relative to the events that might have occurred, and "thus to be quite sensitive to the rate of experience relative to the change in the world" (p. 332). Secondly, experiential learning tends to close the door on experimentation, according to March. It is fairly easy for a fast learner to fall into a pattern of repeating rewarding behaviour, and to stop reaching for the best possible performance. This can mainly be attributed to the ways in which strategies, competence and aspirations adapt simultaneously. Thirdly, experiential learning is not a good way to learn theories of behaviour. The starting point for March's line of argument is that if behaviour conforming to one theory produces rewards, the other theories will tend to be neglected.Because of these problems, simple experiential learning in organisations is a flawed process. However, research and consultation can supplement this learning; not by attempting to substitute it but by helping to mitigate the limitations of ordinary and experiential knowledge.

Fujimoto (1999) avoids the problem of the limitations associated with experiential learning by distinguishing between "routinised manufacturing capability" and "routinised learning capability" on the one hand, and "evolutionary learning capability" on the other in his study of learning in the Toyota Company. Evolutionary learning capability, he argues, is a "nonroutine ability that affects creation of the above routine capabilities themselves through irregular processes of multi-path system emergence" (p. 17).

4. Towards an analytical model – design and learning

A qualitative model can be created by establishing causes and effects between internal variables, expectations, and contexts (Barth 1966). This model might appear to be similar to a quantitative model, but the variables are assigned with qualitative values, not numbers. The model is subject to empirical testing, and with the same values on the variables, the same result can be expected. Thus, different values on the same variables can provide other results. This concerns an analytical generalization where the transfer value might be larger than the case itself.

Creativity, problem solving, decision-making, and attitude change, are according to Kolb (1984) other words for experiential learning. Previously in this paper, problem solving was presented as one of two paradigms in design. The other mentioned paradigm is puzzle making, which can be connected to creativity. This part of design work, was related with «playing jazz» earlier in this paper. Decision-making is an obvious part of design, where decisions on some parts must be made in order to advance processes, even if it might be necessary to make changes later. In addition, attitude change can be connected to accommodative learning (Illeris 2009) and re-learning (Kolb 1984). During the design process it is imaginable that attitude changes are connected to the way designers and engineers work together, e.g. when transitioning the collaboration to Big Room organizing. Innovation can also be connected to design, especially when the design in question has something unique about it, e.g. signature buildings. In the innovation literature, learning is considered as a fundamental process for innovation, and knowledge as the most strategic resource.

Another possibility is to relate design to the value shop model for value configuration (Stabell & Fjeldstad 1998). This model, which is an alternative to Porter's value chain concept for intensive technology (Thompson 1967), is represented as a circle of five generic activities: problem finding and acquisition, problem solving, choice, execution and control/evaluation. When the participants have reached the control/evaluation phase, the circle can be repeated if it is desirable. The relevance for design in the value shop model becomes obvious when we think in terms of puzzle making and problem solving, where problem finding and solving, and choice can be related to reflection and abstract conceptualization in Kolb's learning theory. Furthermore, execution is the equivalent to active experimentation, and control/evaluation can be considered as concrete experience.

Experiences indicate that the design of complex construction projects gradually matures. The designers learn gradually during projects, thus getting a better understanding of the scope, and the issues are solved gradually towards a "good enough" design. In the context of design theory earlier in this paper, it is mentioned that design tasks includes «the joy of discovery, and the frustration of fruitless explorations». In other words, there is much trial and error in the early stages of design, and trial and error is, in this context, an apparent part of the learning process with active experimentation, concrete experience, and reflective observation/evaluation. Concrete experience is, however, virtual as the drawings represents a model of the real world. Furthermore, abstract conceptualization will be included in some cases, e.g. during structural analysis.

4.1 A minor case study illustrating project planning and learning

In order to advance the understanding of the design process and the respective learning processes, we provide an example from a rehabilitation project of a villa (Table 1). The villa was originally constructed in 1953 during Norway's post-war period. The building was in a poor condition, compared to modern requirements for indoor climate, insulation, bathroom, etc.

Table 1. The design process and the respective learning processes in a villa project.

Building authorities	The client	The architect
	The client has a vision of upgrading the building to modern standards. He wants to elevate the ceiling to make room for a loft with an ocean view. In addition, he wants to upgrade the building in accordance to the latest energy standards.	*The architect pays a visit, and discusses the vision with the client. The architect inspects the building in question, and then he sits down and starts sketching the new improved version in his notebook. Based on the knowledge he has acquired through experience, he is able to quickly understand how to implement the upgrades efficiently, e.g. create a new entrance, which gives access to both floors including stairways and storerooms.*
	The client discusses the upgrades with the architect in several iterations. One of the first changes in regards to the architect`s suggestion is the idea of building a conservatory. The client provides the architect with an idea from a magazine. He encourages the architect to come up with additions and enhancements to the conservatory. The alternative that the architect provides is chosen after discussions of functionality and esthetics.	
Preliminary meeting with the local building authorities.	*The idea of partitioning the lot is put on hold after the meeting, as it requires rezoning.*	
Approval that the submitted drawings can be treated as an exemption from the zoning plan's height requirements.	*Application for building permit. None of the neighbors complain.*	
Requirements that the drawings set absolute requirements for legal height, and that the apartment downstairs will require a new application.	*The client makes an effort to adapt the drawings to the requirements from the local authorities. The apartment downstairs is removed from the drawings in order to prevent a delayed startup.*	*The architect adjusts the drawings in accordance to the requirements of the local authorities.*
The local building authorities approve the drawings.		

After the first visit from the architect, the drawings were revised several times throughout the following months. However, the major concept and facade of the building was mainly decided during the two hour long visit by the architect. When the client had started the design process, changes was generated through internal discussions in the client's family, discussions together with friends, and by studies of other construction projects, etc. Clearly, when the client is participating in a construction process, the buildings in the environment are observed in a new way. Ideas and inspiration are absorbed when observing and analysing other solutions. The final project change gradually, and in the context of this simple example the learning is especially happening for the client.

5. Conclusions

The paper verifies that learning is a central phenomenon in project planning, however, this version is unable to provide a complete analytical model of the phenomenon.

Future research will focus on developing an analytical model of learning in engineering. Such a model should in particular be able to uncover that design projects mature progressively through interactive processes with strong reciprocal and sequential dependencies.

Enhancing Student Learning Through Formative Assessment in an Enquiry Based Setting: Some Reflections

Lloyd Scott
Dublin Institute of Technology
Lloyd.scott@dit.ie

Abstract

Across Higher Education and Further Education there is strong research evidence that assessment has a strong link with learning and a key factor in this link is formative assessment. The aim of the research project was to establish if a deeper understanding and application of enquiry based approaches to student learning could be achieved through the implementation of Enquiry Based Student Learning where continuous formative assessment strategy was adopted. Through an action research approach, the qualitative data gathered and analysed from questionnaires, focus group interviews and reflective diaries culminated in findings to show that this learning paradigm significantly improved the competence, understanding, motivation and confidence of those participating in the research. The main recommendations arising from the study were that a form of student-centred pedagogy such as enquiry based learning aligned to continuous and formative assessment could be used to better reflect projects and problems typical of those found in real-life industry situations.

Keywords: Assessment, Enquiry based learning, action research and FALLS

1. Introduction

Traditional lecture-based teaching methods are being replaced or supplemented by approaches which call for reframing the roles and identities of both teachers and learners. Enquiry-Based Learning (EBL) is one such approach. This paper reports on a study investigating the perceptions through reflection of staff and students involved in an EBL capacity building through a formative assessment approach project in a construction management undergraduate programme. An action research methodology offered an appropriate framework within which to explore and understand the formative assessment driven approach to enquiry based learning in this course and offer reflections about it effect on student learning. The findings are discussed using sociocultural learning concepts relating to activity theory and communities of practice. The paper concludes that EBL may improve the quality of teaching and learning in higher education, particularly in the context of built environment education, but careful consideration should be given to the dynamics of the specific context in which it is introduced.

2. Exploring the Landscape of Built Environment Higher Education

Education, as defined by Dewey (1938), is fundamentally about the teacher and the student and the transmission of knowledge, skills and values. This process has always remained the same. However, the manner in which the process occurs today has changed dramatically.

The BE as a holistic entity has changed considerably over many decades. These changes have been in areas as diverse as technology, materials, security, planning, utilities, design, management and finance. Involved as educators and researchers, the community of the BE has responded to these changes: it produces the 'change-makers' and continues to play a vital role in the management of change through the formation of craftspeople, graduates and researchers and the production of knowledge. Since the times of Aristotle and Plato society has found it desirable to categorise the different forms of knowledge in an attempt to make the world more intelligible (Gaarder, 1995). Ratcliffe (2007) proffers that while the Built Environment is both vague and elusive it is a generic phrase of distinction and pertinence and is best portrayed and understood 'as a set of processes' rather than one single entity. This set of processes includes planning, design, construction, regulation, finance, transportation and information. Griffiths (2004) describes it as a range of practice-orientated subjects concerned with the design, development and management of buildings, spaces and places.

In HE the discipline of BE has begun to make significant headway as a recognised discipline where schools of BE have been set up. While school and department configuration is often dependent on the culture of a HE institution, reference to BE is an acknowledgement of the existence of this discipline. In the Irish HE context, while still at a developmental stage, the field of BE has begun to be recognised and embedded as a distinct discipline with BE schools and faculty emerging in the organisational structures of HE institutions across the country.

There is a distinctly defined structure to the education of BE professionals in the US where reference to the term BE is not preferred. The BE domain is not a recognised entity, as it is in a European context. This is because the industry is more fragmented than elsewhere. Each domain/discipline has its own identity and it would appear that each performs independently. This fragmentation relates very much to the way the players in the industry act out their roles. Historically, the education of construction professionals has been aligned with the way the industry presents itself. An aspect that has an impact on where programmes are positioned is the culture and make of a university. There are a number of common approaches that have been adopted by universities that include:

Architecture aligned with construction management/science

Engineering where CM is aligned with engineering focused programmes.

What is much in evidence is the need for structured and embedded professional and vocational skills, knowledge and competencies for the future AEC experts and that schools where students are engaged in the collaborative learning are advancing toward this.

2.1 Enquiry Based Learning

Enquiry based learning (EBL) has the potential to develop students as a scholar (Hodge et al, 2008). It provides opportunities to engage with a range of different learning experiences and styles and, in turn, may lead to an innovation (Healey, 2005) and represents a shift away from more passive methods. This approach involves the transmission of knowledge to students to more facilitative teaching methods through which students are expected to construct their own knowledge and understandings by engaging in supported processes of enquiry, often carried out in small groups. In the context of this piece of research, it is important to highlight the student voice. For example, one of the student taking the course remarked on their experience that:

'You go out of this class with your head buzzing, rather than feeling you've just passively sat there listening to what the lecturer had to say. You can't be passive, you have to be involved and committed on this tasks set' (student D)

Research into EBL proffers that it can improve the student experience, with the potential to enhance recruitment, satisfaction and retention. However, it should be pointed out that both students and staff need to be supported when making transitions in adopting or adapting to new approaches to teaching, learning and assessment, especially where more open-ended approaches, such as active learning, is involved in EBL (Kahn and O'Rourke, 2005). EBL is a constructivist pedagogy that intends to develop deep learning by allowing learners to use an enquiry-based approach to engage with issues and questions that are real and relevant to the subject being studied (Milentijevic et al., 2008). It also places students in realistic, contextualised problem solving environments where projects can build bridges between phenomena in the classroom and real-life experiences (Blumenfeld et al., 1991). Projects set can have varying complexity, but all will relate in some way to the fundamental theories and techniques of the chosen discipline (Mills and Treagust, 2003).

2.2 Formative Assessment Strategies

Assessment is a powerful driver of learning and lies at the heart of the learning experience. Formative Assessment within this EBL situation involved methods that focused on understanding rather than just memory recall and surface learning where elements of the Formative Assessment Led Learning Strategy (FALLS) were shared and explored by the lecturer with the participants. It was in an effort to change the perception that learning and building on your experiences is a challenge and it is not just about getting the correct solution; but more a move to gain an understanding of the meaning of the project task, that motivated this research study. As assessment 'drives learning' (Boud, 2007, and Boyd, 2007) the design of a EBL approach linked to an appropriate assessment strategy would result in meaningful and enhanced learning in the subject area. So, linking learning tasks with assessment tasks provided the platform for this project. It was found that the project tasks used in the research study needed to be carefully constructed and related to real world design problems. Previous work on tasks suggests that they serve as critical links among student motivation, cognition, instruction and learning (Blumenfield et al, 1991).

Many tools can be used for assessment within EBL, but all are pushing towards the common goal of creating a framework to assist learning and understanding through formative assessment (see table 1, FALLS conceptual framework). This framework should support students in their assessment, self-assessment, and presentations whilst also facilitating reflective learning (Scott and Fortune 2013) The integration of learning, instruction and formative assessment within EBL is necessary and one cannot generally go without another The approach to this project was based on those principles and embedding four elements of FALLS.

In EBL, the process of constructing an applied distinct project (in this case a number construction detail design task), also focuses the student or student team to think through the steps of the process and complete tasks in a logical sequence, similar to a construction team in the workplace. As there was a sequential, logical and reflective path to be followed in this process, and where an understanding had to be achieved in order to progress through the design, the reason for rote learning was practically removed and it was a case of learning by doing. It is the belief of this researcher that this is more representative and worthwhile to built environment students to achieve an understanding of why and where they can use their experience and previous knowledge directly in their approaches to professional life and in many instances their own personal life.

1) assessment for learning conception
2) student-centred learning pedagogy
3) preparation for feedback
4) feedback methods and dialogue
5) staff development
6) staff-student relationships.

Table 1 FALLS conceptual framework

3. Research Methodology

In the educational environment research exists in many forms and can range across a variety of topics and engage in a diverse array of methodologies and methods to answer particular research questions. All research, including Built Environment (BE) educational research, needs to be subjected to careful and considered methodological assessment and rigour. Traditional forms of theory are grounded in a logic of binary divides (McNiff & Whitehead,, 2005) and thus can tend to exclude the notion of practitioner research. For example, this might be an academic applying other people's theories to their practice or, as is the case here, a researcher engaged in examining other people's practices and extracting a theory or framework. The primary concern, in relation to methodological issues, is to ensure that the research is conducted within the parameters of a methodology that appropriately addresses its aims. Therefore, an approach that accommodates change, such as an action methodology or participatory action research methodology, seems to offer an appropriate framework within which to explore and understand the assessment practices of BE academics on undergraduate higher education programmes.

The research itself is a study into the views of students and the researcher in the field of construction management on assessment followed by an exploration of FALLS practice that was developed to help to lead to an improvement in how students learn in construction education. The action research case study that is being presented involved cycles of interactions between the researcher and the research subjects that had two separate objectives:

1. Participant learning to build capabilities and enhance ability to understand and generate constructive behavioural change through reflective action on assessment practice

2. Generation of research findings for the researcher on the usefulness of FALLS as a tool to enhance such actions by the participants as improving their learning.

Iterative cycles of learning and development of research understandings, however, can be challenging to balance, as the motivations and benefits of the different parties can compete with each other (Steinfort, 2010). In this case study, the AR process described by Brannick and Coghlan was adopted because the research objectives aligned with their broad definitions of action research should be (2010, p. 4):

- Research in action, rather than research about action
- A collaborative democratic partnership
- Research concurrent with action
- A sequence of events and an approach to problem solving.

A significant reason an action research approach was chosen was because it combines both learning and generation of new research knowledge through a series of iterative cycles across multiple cases. This was considered to be an ideal way to explore the research objectives in such an emergent situation. The learning aspect of the research is that the participants learn some techniques that they then try to implement as part of their own environment and then reflect on what resulted from that (and ideally go through iterative cycles to further develop their capabilities on the use of the methods to continue to enhance their ability to influence others and enhance outcomes). The research aspect is to understand how the application of the FALLS impacted the participants. In these situations, it was not possible to predict what the outcomes would be and the participants needed to use reflection before and after the intended action in order to optimise the outcomes and determine reasons as to why they got the results they did. The role of the researcher in this research was to guide the participants in the use of the FALLS, assist with planning the intended interventions and collate reflections from the participants. An aligned perspective was presented from McKay and Marshall (2001), who proposed the 'dual imperatives of action research' as being problem solving (a form of learning within a specific issue context) and a contribution to research. They explained the difficulties of researching the process being taken whilst actually applying the process to create outcomes in terms of developing solutions to real problems, and they suggested the AR approach was ideal for this.

Action research – which is also often referred to as Participatory Action Research (PAR), community- based study, co-operative enquiry, action science and action learning – is an approach commonly used for improving conditions and practices in a range of environments (McNiff &Whitehead, 2005). It can be used to involve practitioners conducting systematic enquiries in order to help them improve their own practices, which in can offer the potential to enhance their working environment and the working environments of those who are part of it – students, practitioners (contractors), clients, and the like. The purpose of undertaking action research is to bring about change in specific contexts, as Parkin (2009) describes it. Through their observations and communications with other people, action researchers are continually making informal evaluations and judgments about what it is they do. This approach can offer an embedded approach to reflection and so lead to improvement.

4. Analysis of the research

This research study was carried out on just one course from a very large curriculum in which rote and traditional forms of learning is seen to be extensive. Data collection took place over the period February 2014 to June 2014 for the research investigation part of this enquiry. During that period and beyond, the data collected were assembled and analysed in a phased approach. Each phase of the research process was documented and the data recorded appropriately as per good practice.

With very few exceptions, the students who participated in this study agreed that they found the FALLS method of learning, teaching and assessment more productive to their learning needs, more engaging through challenging real-life design work, and more resourceful in providing them with the competencies they need to work within their chosen discipline. What is generally agreed throughout the research literature is that modern society requires a fundamentally different conceptual discourse for assessment (Clegg and Bryan, 2004). Such assessment activities should not only address the immediate needs of certification to students on their current learning, but also contribute in some way to their prospective learning (Boud and Falchikov, 2006).

Society now demands more than passive graduates who have complied with a rigid regime, and employers and professional groups are placing expectations on institutions to deliver graduates who are prepared for and can cope with the real world of work (Boud, 2007). Student-centred learning can foster knowledgeable, competent, reflective and committed learners (Mentkowski, 2006), that are more prepared for the unorthodox type of real work problems that are typically associated with engineering and built environment disciplines. Students may escape from poor teaching through their own activities, but they are trapped by the consequences of poor assessment, as it is something they are required to endure if they want to graduate (Boud, 2007). The more we can engage students in assessment activities that are meaningful to them and which contribute to their learning, the more satisfying will be their educational experience (Boud, 2007).

5. Discussion

What emerged from the focus group sessions and individual feedback was that most participants reported that they had never used formative assessment methods in any previous class setting. At the early stages of the research the reasons for this were not evident, as most of the participating group suggested their level understanding of assessment was that it was about '*exams*'. However, further analysis of the data showed that although their understanding levels were sufficient to learn construction detailing for summative assessments, the relationship and link between these calculations and real-world construction methods tasks was unclear to most students.

In a focus group session, student E commented that, *'I always had the ability to to prepare well for my exams, but I didn't know why I was doing them'*. There appeared to be general agreement with this from the group. Student C also reported that *'I didn't know where in construction or on site these methods could be used, they were just written on the board and we were told to follow them for the exam'*. From the student's perspective there seemed little reason than to continue with any effort to understand, when they could see no practical value to do so. Based on the evidence of the projects submitted by students, along with the research data analysed, it appears reasonable to suggest that the majority of the students have the ability to learn construction detailing and apply that knowledge and are happy to use them once they can see a clear and practical purpose to do so. There was a general consensus among research participants that having gone through the FALLS method and in construction tasks they could now use this knowledge and apply it to a real building situation. Student F commented that *"I could now see what the construction details were doing in the project tasks; it's more like what is expected of us in industry"*.

There was general consensus among each group that learning through FALLS was a better learning experience than they had previously. Many students expressed a sense of enjoyment in the learning experience and thought that other courses should be delivered in this manner. During the focus group sessions, it was most interesting to listen to students still discussing knowledgeably with each other, the approach to solving their particular tasks they had used in the various projects a number of weeks previously. When questioned on this they expressed an ease of understanding having used these formulas to produce an end product. Student A made the point that, *"when I did construction calculations before I finished with a number that meant nothing. This time I had to go and find certain aspects to match and also make sure it would fit in the space. Now it means something to me"*. Most of this group agreed that they now had a deeper understanding of this subject and they had also learned where they could be used within construction detailing.

From the research data, there is strong evidence to suggest that the students strongly engaged and were more motivated to broaden their learning about this subject area. When given an opportunity to learn and apply it to their chosen field they willingly undertook the tasks and were interested in coming up with a workable solution. Most of the comments relating to this in the focus group interviews and classroom discussions concurred that studying questions and subjects for an end of term summative assessment was not increasing their competence, knowledge or skills in the chosen area of study. In fact, all of the focus group participants agreed with the words of student F; *"it would have been great to do all our subjects and design them within a project building. I would definitely have learned much more about construction management"*. In addition, student C followed on to say; "*if we were assessed on this it would be much better and we would learn far more than trying to remember questions for an exam".* Student B also made the point that; "*it would be great to see how all the different systems like project planning and on-site supervision join up with each other in a building project. At the moment we just do everything separately for examinations. It is just read out and I can never see how they all link together*".

It would appear from the responses that the students indicated complete satisfaction with the FALLS approach but, more particularly, the linking of the assessment to their learning. The use and practice of applied processes that are task orientated with feedback contributed to a distinct increase in (construction) confidence levels over the course of the research study. With this increase in confidence, many students throughout the research period, showed initiatives to extend their (construction) skills beyond the curriculum. An example of this was the extremely high attendance during and after class throughout the semester. It is the contention of the researchers that students attend class if there is a reason to.

One of the major aims from this research project was to provide a platform that enabled students to gain a deeper understanding of construction technology and its application in the construction process through a task orientated approach with a formative assessment focus. The findings of each individual action research cycle hold that the majority of those who participated in the research reported a distinct increase in both their level of understanding and in their competence, in the use of applied construction methods.

The early interviews with students indicated that their confidence around the use and understanding of the application of calculations was lacking. However, later findings revealed that they gained confidence in their knowledge and understanding through the task orientated approach. Student B commented, *"The tasks we did helped me get a better understanding of why and where the construction details could be used to building design. I now also feel more confident in my ability to use them in relation to my job".* Most felt they would now be more able to accomplish many design- orientated tasks and work related problems from the experience of this approach. The feedback from the majority of students together with all of the research findings has shown that a task orientated approach with the underpinning of a strong formative assessment strategy, when used in the correct circumstances, has the capacity to create learning environments that are facilitative to deep levels of learning and understanding.

The findings and discussions presented in detail above, along with positive feedback from students during the course of this study, leave us confident to report that we believe a deeper understanding and application of applied calculations and calculations can be achieved through the implementation of FALLS and assessment within a construction detailing module.

In regard to the case study presented, many of those students who participated in the research still make contact (mostly via email, IM, and text messages) about the impact of this assessment approach on their learning. They reflect and report on their memories of our classes and how it allowed them to see and develop a more diverse approach to their learning, but most of all, it provided them with an opportunity to explore and achieve the best in themselves. In sharing this research enquiry and the findings, in no way is it intended to convey a naive, heroic, or triumphal tone. It is nevertheless most rewarding to share the reflections about small change and the transformation that has impacted on a small number of students. The author remains hopeful that that experience shaped and changed their lives for the better.

6. Conclusions

Much current practice as to ways of linking research and teaching reflects tradition, but there is considerable variability in approaches within subject disciplines. Enquiry-based learning, for example, may be infrequent in some disciplines, and occur at different stages of the curriculum in other disciplines. However, innovation is possible, as is shown by examples such as, inquiry-based learning in this case and the use of research based assignments in the

It is hoped that through the sharing, description and analysis of this very concrete action research case study examples, learners, educators and researchers can come to recognise students' intelligences and cultures in the learning environment through dialogues initiated from multicultural literature, while critically exploring hard issues, such as diversity, gender equity, strength and power, and considering multiple perspectives. I do not offer an answer, as there is not a single one: what I do offer are perspectives; my perspective and that of the students who endeavored to problematize their learning issues around assessment as a way to deal with enhancing their learning.

As an educator, much has been learned through action research alongside my students while merely seeking to provide access for all learners to a more structured and beneficial approach to formative assessment. I would like to offer encouragement to all academics and those in education development to begin 'to re-create and rewrite [these] ideas' (Freire, 1970: xi) and to start implementing learner centred responsive pedagogies through deep explorations and dialogues. I would further encourage the use of the FALLS in the classroom as a strategy for challenging the perceived issues that surround assessment practice.

Action research projects test knowledge in action and those who do the testing are the interested parties for whom a base result is a personal problem. Action research meets the test of action, something generally not true of other forms of social research. Conventional researchers worry about objectivity, distance, and controls. Action researchers worry about relevance, social change, and validity tested in action by the most at-risk stakeholders.

Looking to the wise words of Ralph W Tyler (1949):

> *"The real purpose of education is not to have the instructor perform certain activities but to bring about significant changes in the student's patterns of behaviour".*

The real challenge lies in the fact that we as teachers need to bring about significant changes in our patterns of teaching in order to achieve that. All aspects of learning, teaching and assessment should form part of any reflection.

Abstract

The Best Value environment was introduced into the Netherlands in 2006. By 2008 testing was being done by a partnership of Arizona State University and Scenter (private entity led by Sicco Santema). In 2010, the $1B fast track projects were procured by the Rijkswaterstaat, and by 2012, the Best Value approach had become a core practice of the professional procurement personnel. The Performance Based Studies Research Group (PBSRG), the creator and licensor of the Best Value Performance Information Procurement System (PIPS) targeted three industries which shared the management, direction and control (MDC) characteristics of the construction industry: the medical industry, the ICT industry and the professional services industry. The ICT industry has the worst performance even though it has the highest rate of change in its technology. A case study is being conducted with the large, traditional ICT vendor, to see if they can successfully implement the characteristics of the best value approach and overcome the traditional nonperformance of the ICT industry. Their progress and challenges will be compared to the challenges in the construction industry. If the issues are the same the solutions should then be applicable in the construction industry.

Keywords: IT industry, performance, supply chain issues, large organization, Best Value

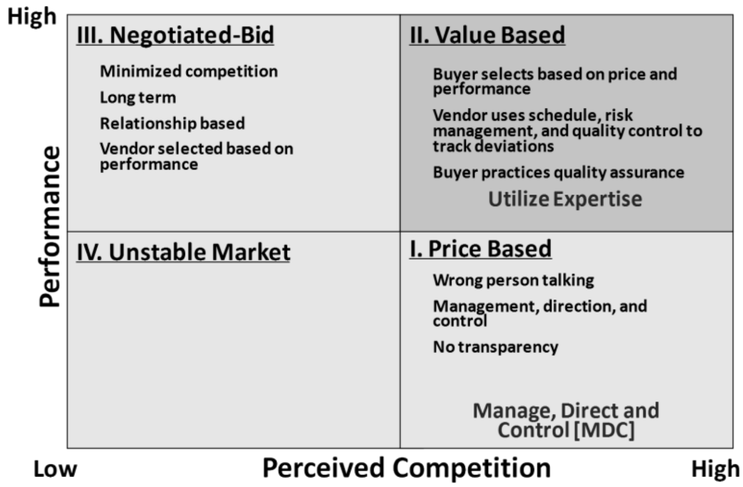
1. Collusion in the Dutch Construction Industry

In the early 2000s collusion was identified in the Dutch Construction industry. The cause of the collusion was identified as contractor greed (Doree, 2004; D. Kashiwagi & J. Kashiwagi, 2011). In response to these allegations the government moved to penalize the guilty parties but discovered that the penalized amounts would be greater than the profit generated by the identified vendors. In order to maintain stability in the industry a few scapegoats were identified and penalized, while the rest of the industry was persuaded to build a case against the scapegoats by providing information on the collusion. Those who volunteered information were promised to be exonerated.

1.1 Construction Industry Structure (CIS) Model

The source of poor construction industry performance has been identified as an owner generated problem and not a vendor generated problem (Figure 1).

Figure 1: Construction Industry Structure (CIS) model



(Information Measurement Theory by Dean Kashiwagi, 2014a, Tempe: Ksm-inc.)

The CIS identifies that the major difference between low performance and high performance is caused by the owner's use decision making, and attempt to manage, direct and control (MDC) to minimize risk, instead of utilizing expertise. The results of this practice include (Kashiwagi, 2014a):

1. Poor performance
2. Higher costs
3. Inefficiency
4. Decision making
5. Need for relationships to be formed to solve problems
6. Lower value of expertise
7. Commodity practices
8. Non-transparency (an environment where the source of the problem is not easily identifiable).

The concepts of the CIS was being presented in CIB conferences in Trinindad, Tel Aviv and Singapore, and eventually led to a fellow CIB member (George Ang, Ministry of Housing). George Ang then brought Dean Kashiwagi into the The Hague, Netherlands to present to the various ministries in 2004.

2. New Academic Research Approach

At this time, the construction management academic research experts in the Netherlands did not come to consensus about the CIS model and explanation. It seemed too simple, the overriding concept being that the vendors were at fault, and the Dutch construction management researchers felt that the Dutch culture was different from the American culture. Only one source, Dr. Dean Kashiwagi from PBSRG/ASU proposed that it was the owners and not the vendors who were at fault, and he was using deductive logic, common sense and case study tests in the United States to validate his proposal.

An effort was made by Dr. Kashiwagi to involve more researchers, but his insistence to run industry tests without consensus of all the researchers led to a failed effort. Instead of using the conventional rout of academia, Dr. Kashiwagi, began applying PBSRG's deductive approach, using industry testing with visionary industry personnel to start the research. Bypassing the discussion and consensus of the Dutch Construction Management academic researchers in the Netherlands, Dr. Kashiwagi, went right to the industry and formed partnerships to test out the CIS concepts. Dutch visionaries in one of the major construction companies (Marc Gillissen), multiple visionaries in the Rijkswaterstaat, and a visionary professor in marketing and supply chain at Delft University (Sicco Santema) identified the CIS model explanation and the Best Value (BV) PIPS as a solution to change the environment of the delivery of services resulting in the following actions (D. Kashiwagi & J. Kashiwagi, 2011):

1. Heijmans Construction licensed the Best Value Performance Information Procurement System (BV PIPS) from ASU.
2. Rijkswaterstaat was also licensed with the BV PIPS technology from ASU.
3. Scenter (private consulting company led by the visionary Sicco Santema) and the Delft University were licensed with the technology.
4. Scenter was trained by PBSRG. They ran small successful BV PIPS tests in 2008-2009 (Van de Rijt, Hompes & Santema, 2010).
5. Rijkswaterstaat ran a huge test by procuring $1B "fast track" infrastructure projects using BV PIPS (called Best Value Procurement or BVP) assisted by Scenter and PBSRG.
6. The fast track project results using BVP minimized procurement transactions and costs for all parties by 50%, vendors reduced construction time by 25%, and tests confirm that the CIS model is accurate and 90% of all project cost and time deviations are caused by the owner. They also confirm that the MDC activities of the owner's project managers was the source of most issues (Van de Rijt, Witteveen, Vis & Santema, 2011).
7. As a result of the "fast track" projects, NEVI (third largest organization of professional procurement personnel in the world) licenses the BV PIPS technology from Arizona State University (ASU) and begins to educate and certify all procurement personnel in BVP and the CIS and the underlying logic of the BV PIPS approach which is called Information Measurement Theory or IMT (PBSRG, 2012). The BV PIPS approach which moves the paradigm from the price based MDC environment to the utilization of expertise environment is now one of the major thrusts of NEVI. They have recently hired a new Director of BVP education and are expanding their offerings to assist all stakeholders in understanding of the BV PIPS approach.
8. The RISNET organization comprising of risk managers and professional engineering groups also licensed the technology from ASU.

The history of changes within procurement paradigm in the Dutch construction industry along with dominant project successes validated the CIS model. The model and the BV PIPS or Best Value Procurement (BVP) is now accepted and used as a mainstream model in the procurement of services in the Netherlands. The traditional academic research model of performing a literature search of existing concepts, proposal of a theoretical solution based on the literature search, survey of industry experts to identify which industry characteristics are most influential in the collusion, and presentation in academic journals to seek consensus in the academic world was not used due to the extensive time and impracticality. The process would be too lengthy, would not assist the industry in a timely manner, and would utilize opinions of industry and academic personnel that were “a part of the existing problem.” The Dutch results are supported by the following results of PBSRG/ASU in the United States and other countries:

1. 22 years of research testing, $16M of research funding, 1,800 tests, 98% customer satisfaction delivering $6B of services (PBSRG, 2015).
2. Most licensed technology (45 licenses) developed at ASU, one of the top research universities among universities without a medical school.
3. Two five year longitudinal studies identify the client and their representatives as the largest source of project cost and time deviation. Vendors create minimal risk when transparency allows the identification of the sources of risk (D. Kashiwagi & I. Kashiwagi, 2014).
4. 250 journal conference publications showing that management, direction and control (MDC) results in poor performance. (PBSRG, 2015).
5. Validated the CIS or IS model, and identified that the paradigm must be changed for delivering construction services (Kashiwagi, 2014b).
6. CIB W117 committee on the Use of Performance Information in the Construction Industry has done research work in seven different countries and 32 different states in the United States validating the same concepts.

3. Problem in the ICT or IT Dutch Industry

The delivery of services in the IT industry is perceived as being non-performing. The following has been documented on the nonperformance of the ICT industry:

1. ICT non-performance is estimated as high as 75% (D. Kashiwagi & I. Kashiwagi, 2014).
2. Major consulting company claims that the projects are too complex, and the complexity is causing the nonperformance.
3. New project management model, the agile approach, which maximizes communication and documentation, movement in smaller increments of time, and works from beginning to end instead of from the end to the beginning (Scrum Alliance, 2013).
4. Dutch government inquiry is held to identify the source of the ICT industry nonperformance and the large amount of resources being wasted on ICT projects. The result of the inquiry shed no more understanding of the problem (Tweede Kamer, 2014).

One of the larger ICT industry partners was identified as being in collusion with Dutch government officials (Zembla, 2014). Even though the company has not been convicted of crime of collusion, the company was cast in a poor light. At the same time, PBSRG was notified of another large government client was having problems with another major ICT vendor on a best value project.

4. Proposal

Past research results show that the client/owner is the biggest source of risk in the delivery of construction services. Because the source of risk is not technical (client/buyer using MDC to deliver projects and minimize risk), the authors propose that the problem is not a technical problem (complexity of the technology, lack of technical expertise, or complexity of the requirement). The authors propose that the CIS or IS, identifies that poor performance and collusion is caused by the client attempting to manage, direct and control (MDC) projects. The authors propose that the client is creating an environment which is:

1. Nontransparent, confusing and based on relationships.
2. Does not utilize expertise.
3. Filled with decision making from non-experts.
4. Resulting in inefficiency, ineffectiveness, and poor performance.
5. Not understanding what risk is and how to utilize expertise because experts have no risk.
6. The areas of risk management and project management have to be redefined and new paradigms must be utilized to increase the performance of the ICT industry.

5. Methodology

1. The researchers will search and identify an ICT vendor that does not utilize MDC to deliver their service. Their performance will be identified.
2. If the performance is dominantly higher than the industry performance of 25% success, the authors will investigate if the problem of MDC is in the ICT industry.
3. Identify a large traditional ICT vendor and identify if they have a bureaucratic or MDC environment.
4. Identify if the large traditional ICT vendor has a performing project or a BV project.
5. Analyze the project to identify what made the project different.
6. Analyze the owner/client of the performing project and identify what they did differently.
7. Also identify if the client/owner visionary is facing resistance from MDC personnel in his own organization.
8. Identify an effort with a large ICT vendor responding to BV project request that resulted in the client using decision making and MDC to eliminate the vendor’s BV effort.
9. Identify the difference between the price based and BV environments, and identify the difficulty for a large ICT vendor to change into a BV oriented vendor.
10. Analyze the results of the case studies to see if the environment delivering ICT services is in the price based arena resulting in low performance.

6. Research Case Studies

Schuberg Philis (SBP) is one of the ICT companies in the Netherlands that is known for their high performance and unique company structure (D. Kashiwagi & I. Kashiwagi, 2014). After studying SBP it was confirmed that SBP was an expert company that delivered high performance (See table 1):

Table 1: Schuberg Philis Overall Performance Line

1. They are the top rated ICT vendor in the ICT infrastructure area (in every category measured).
2. They have a project performance of 89.36% on time, 95.74% on budget, and 93.62% customers satisfied on 47 large projects in the last six years.
3. Of the six most critical ICT providers that support financial vital infrastructures as stated by DNB (same function as Federal Reserve Bank); they are the only vendor with 100% customer recommendation for outsourcing.
4. In the last four years, their business process uptime performance is 99.994.
5. Their customer satisfaction rating was 8.9 in 2013 – highest in the IT market for 7 years in a row, 2 full points above the market average (6.9).

Some unique characteristics about their organizations is that (D. Kashiwagi & I. Kashiwagi, 2014):
1. They have no MDC.
2. They have very high performance.
3. The authors conclude that Schuberg Philis is a BV company that delivers high performance.
4. They prove that if a vendor is BV oriented (no MDC), they will deliver very high performance.

Table 1: SBP Performance Metrics

The traditional ICT industry is in the MDC environment resulting in low performance. The authors will identify large traditional ICT vendors and show that they are in the MDC or bureaucratic environment.

6.1 Case Study of Large Traditional ICT Vendor

One traditional ICT Vendor was accused of being in collusion. In their efforts to change the public perception and mentality of the company the vendor began to investigate the Best Value Approach. As the BV approach stressed "win-win" relationships and utilization of expertise to deliver high performance and low costs, the vendor formed a BV core group to achieve these results. The BV core group discovered

#	*Criteria*	*Metrics*
1	*Total # of projects in last 10 years*	*991*
2	*# of large projects (€150K- € 3.3 Million)*	*47 (72)***
3	*% of large projects on time*	*89.36%*
4	*% of large projects on budget*	*95.74%*
5	*% of large projects customers satisfied*	*93.62%*
6	*Highest customer satisfaction 7 years in a row (Market Average)**	*8.9 (6.9)**
7	*Recommended by customers by year*	*100% 5 years in a row*
8	*Business Process Availability past 4 years*	*99.994%*

* Market average was taken from 2014 Giarte Report
**72 projects existed however; documentation older than 6 years was discarded and not available.

that many of the experts within the company were already thinking and acting with the BV approach. An example of this was identified as a performing project at the Port of Rotterdam.

The project was investigated to identify its status. Five key participants on the buyer's side were interviewed and the status of the project was reviewed. Findings include (Port of Rotterdam project participants, personal communication, June 6, 2015):

1. The owner/client's procurement manager utilizes BVP as the procurement approach.
2. The client PM faces resistance from own organization.
3. BV approach required a change in paradigm from MDC to utilizing expertise on both the buyer and vendor side. Required vendor and buyer to go through a learning curve.
4. The paradigm shift had been a big challenge to the project for both the vendor and the buyer.
5. The project is successful, and the project team identifies the project as a success.

Table 2: Project Participant Interview Summary Responses

#	*Criteria (10 is strongly agree, 5 is don't know, 1 is strongly disagree)*	*Results*
1	*The owners' inability to utilize expertise of expert vendors is a source of risk and poor performance.*	*8.2*
2	*Unlike Schuberg Philis, which was already practicing a BV approach, many larger traditional companies (using MDC and reactive behavior) have a very difficult time changing to the BV approach.*	*7.6*
3	*Owners also have difficulty changing from the MDC approach to the best value approach.*	*8.2*
4	*Until larger vendors change their approach, the industry will not have the momentum to change paradigms.*	*6.2*
5	*Large owners would have a difficult time changing the traditional buyers and project managers' paradigm.*	*5.8*
6	*The owner have a difficult time implementing a clarification period.*	*5*
7	*The implementation of a clarification period would tremendously increase the project performance.*	*9.4*
8	*A clear plan which includes the functions of all the stakeholders would increase the performance of the project.*	*8.2*
9	*The best value approach changes the project management, risk management and the definition of risk (what the vendor does not control).*	*8.6*
10	*Decision making is reduced if the expert's plan is utilized.*	*8*
11	*The best value approach is the optimal approach to increase project value and performance.*	*8.4*
12	*The expert vendor can utilize the best value approach even if the selection methodology was a more traditional relationship award, if it implements a clarification period, a weekly risk report, and creates transparency.*	*6.6*
13	*Rate the vendor's performance (1 is unacceptable, 5 is average and 10 is outstanding).*	*8.4*
14	*What would the performance be under the traditional approach?*	*5.6*
15	*Was the performance delivered by the BV vendor higher than would have been delivered under the traditional approach (MDC)*	*4 out of 5 (yes)*
16	*Is the traditional PM model (MDC) accepting of the BV approach?*	*5 out of 5 (no)*
17	*Did the PMs have to change their paradigm to do BV?*	*3 out of 5 (yes)*

6.2 Case Study of Large Traditional ICT Vendor Submitting on a BV Effort

This large traditional ICT vendor attempted to win a Best Value project. Being coached by an A+ BV certified expert the vendor understood the BV process and knew they would require true experts in order to secure this project. Due to this the ICT vendor put their best experts on the project; one of their best project managers and best technical experts on Oracle. In responding to the request for proposal of the buyer they attempted to show how they could provide a high expertise in relation to the buyer's project objectives. In one of the three two-page documents some of their main substantiations of their expertise include (personal communication, July 7, 2015):

(Objective 1 & 4): The key personnel of the supplier are an experienced project leader Transition and an experienced service delivery manager, which contributes to the objective of unburdening with regards to system management and a risk-free and effective transition The project leader Transition has successfully:

1. *Brought 2 ERP environments to system management through a transition in the past 4 years. The results were:*
    a. *Deviation regarding time and budget 0% (Fixed Price projects);*
    b. *Average project budget €5.1 million;*
    c. *Customer satisfaction 8;*
    d. *On average more than 10 interfaces and 20% custom work.*
2. *Taken care of 3 ERP implementations in the past 7 years, including decharge. The results were:*
    a. *All 3 > 3 million;*
    b. *Deviation regarding time and budget less than 5%;*
    c. *Customer satisfaction 8.*
3. *Implemented information security 1 time at a government agency so client and supplier are compliant to the information security policy (BIR).*
    a. *Deviation regarding time and budget 0% (Fixed Price Project);*
    b. *Budget 70 days;*
    c. *Supplier received decharge.*

The service delivery manager was responsible at two EBS & BI clients for 3.5 years for the delivered services (FAB, TAB and TB) and achieved the following results:

1. *Client 1:*
    a. *System management budget €325,000 per year;*
    b. *Customer satisfaction: 8;*
    c. *17 EBS modules, 16 interfaces and 164 custom work components;*
2. *Client 2:*
    a. *System management budget €1,860,000 per year;*
    b. *Customer satisfaction 8;*
    c. *22 EBS modules, 12 interfaces and 157 custom work components;*
    d. *Score of 8.4 for availability and 7.1 for performance EBS platform*
    e. *Availability 99.98% (24/7)*

(Objective 5): *Provider allocates a certified experienced information security specialist on the project that has a proven track record in meeting the compliance of managed systems. This contributes to the objective of fulfilling all requirements regarding the protection of personal data and information security. Supplier allocates an information security specialist:*

1. *Certified CISSP (associate)*
2. *Who ensures the information security policy for 55 ERP contracts (34 EBS, 21 SAP) and performs 6 compliancy checks every month.*
3. *Finds an average of 1 customer security incident per month and manages it.*
4. *Supplier has been audited by an external party and holds the certificates ISO/IEC 27001 (Information Security for all types of organizations). 130 system management contracts are part of the certification. The system management contract of Buyer will also fall under this.*

(Objective 1 & 3): *Supplier achieves an availability of the production environments of at least 99.8%, 24*7 (excluding agreed maintenance slots), this contributes to the objectives of Buyer for continuous availability, availability outside regular office hours and makes working from home possible. Supplier achieved this high availability in 2014 at three similar clients with EBS/BI system management contracts:*

1. *Average availability production 99.95%;*
2. *Average number of managed interfaces 17;*
3. *Average number of users 1750.*

(Objective 2) *Supplier achieves the desired service levels from the SLA from day 1, this contributes to the effective cooperation with Buyer and in particular with Functional System Management. Performances of the supplier in 2014 are:*

1. *Handled a total of 1294 technical EBS client notifications for 34 system management contracts*
2. *Achieved SLA response time in 91%;*
3. *Achieved SLA resolution time in 92%*
4. *Achieved SLA resolution time for 14 technical EBS client notifications with priority "Very high" in 100%.*

The results of this submittal shocked the IT vendor as they had thought they had provided sufficient information to reflect their expertise to this project. However, the client/buyer rated them neutral rating of six on a scale 2 to 10 in their claims of expertise for the following reasons:

1. Good linking support to performance targets; Applicant thus demonstrates in principle to achieve all project objectives.
2. Applicant shows experienced people which are more likely to have done ERP transitions and less frequently EBS transitions.
3. Many quantitative substantiation of the claims which the question is how verifiable (and dominant) are these numbers? Performance support is limited in relation to the actual Buyer proposed approach. This makes Vendor less clearly understand the mission.
4. Conclusion: Vendor provides a relevant achievement underpinning; here, however, shows no (dominant) added value that justifies a higher score than neutral.

6.3 Case Study of another Large Traditional ICT Vendor Winning a BV Effort

In the initial development phase of the best value approach another large IT vendor began competing and investigating the approach. The Vendor bid and won a telephone/communications integration project. However, due to the buyers and Vendors inexperience with Best Value and the current maturity of the BV approach in the Netherlands key elements of the process were overlooked such as the clarification phase. The project ended in failure with the Vendor unable to deliver the client's expectations and the project reverting back to a traditional approach of management, direction, and control.

Since then, the Vendor has become more involved and educated in the BV effort and has formed a BV core group for the company. The BV core group has become knowledgeable and successful in winning project bids and educating company individuals to deliver high performance, some key indicator of success includes (See Table 3) (personal communication, October, 29, 2015):

1. +/- 10 members (solution consultants, bid manager, project managers)
2. Internal training sessions (since 2013 63 training sessions, > 600 participants)
3. 100% success rate in going to the interview phase of project bids when BV team is part of bid team, 67% when BV team is in a support role (less active role), and 36% when BV team is not involved at any level.
4. 56% success rate in winning bids, 25% when BV team is in a support role, and 18% when BV team is not involved at any level.
5. Vendor is expanding their effort from the sales/marketing group to the project management group and are observing that level of expertise has diminished due to long period of owner's MDC approach to ICT services.

Table 3: Vendor BV core team bid results

Involvement of BV Team	*% to next phase interviews*	*% to next phase: clarification/won*
BV team part of bid team	*100%*	*56%*
BV team support role	*67%*	*25%*
BV team not involved	*36%*	*18%*

7. Conclusion

The problems in the ICT industry are the same problems that were faced in the construction industry. Using deductive logic, it is clear that the ICT industry is having the following issues:

1. A vendor was identified who does not use MDC in the delivery of their service by using expertise.
2. The high performance ICT vendor has no performance issues. Their performance is dominantly better than the other large vendors.
3. The study of their performance shows that they are in the BV environment. A bank study identified the most dominant ICT vendors in the Netherlands. The high performance vendor is one of the vendors.

Two of the other large ICT vendors who are trying to gain the capability to deliver performance were approached. Both vendor environments were in the price based environment (bureaucratic, difficulty identifying expertise, and difficulty in meeting the requirements of a BV effort). Both large ICT vendors were engaged in a BV effort, and both clients had problems in implementing the BV environment due to a lack of understanding of the BV paradigm. In both cases the clients were facing the resistance of traditional approaches to delivering projects. Both clients showed that there must be a paradigm shift in not only the vendor's approach but the client's approach. Both large ICT vendors have visionaries who realized the importance of changing the project management and risk management paradigms.

The research shows that the CIS model can be utilized for any industry. It also validates that the largest source of risk is the owner's decision making, and their use of management, direction and control (MDC) to minimize risk and deliver performance. The authors propose that the use of expertise will reduce project cost and increase vendor profit.

The ICT industry is in the price based environment where the owners are attempting to manage, direct and control (MDC) the vendor to minimize project cost and risk. The ICT industry is facing the same issues as the construction industry. The results of this study propose that the owners can increase project value and minimize project cost by utilizing expertise. By observation of both industries and the case study results over 20 years in multiple countries and cultures, the changing of the environments from a price based environment to a BV environment requires experts who think differently (see into the future before they do a project, identify the project requirements in simple terms that all stakeholders can understand, identify everyone's role in the delivery of the service, and minimize the risk of the project by transparency and not control to assist everyone to see into the future and not be surprised).

The ICT case studies have shown that resistant stakeholders resist because they do not understand the future outcomes, and will cooperate if they can see the future outcomes. This is the requirement of the expert, to simply and create transparency so that all stakeholders can see the future outcomes. This environment requires a new project management approach and a new risk management approach, both of which the Dutch best value effort is working to develop.

This research has also validated through deductive logic and mixed methods the Industry Structure model. It has identified that the owner/buyers have created an environment of collusion through their MDC based procurement systems. The Dutch ICT industry collusion case is no different from the Dutch construction collusion case. The research also shows that the BV model has worked in both industries and can assist vendors in the Dutch ICT industry to improve.

Stakeholder Integration and Innovation Effectiveness in Sustainable Construction Projects

Shaima AlHarmoodi and Mohammed Dulaimi

The British University in Dubai
Email: 120009@buid.ac.ae

Abstract

This paper studies the effect of stakeholder integration in achieving effective innovations to deliver more sustainable construction. The motive is the current global shift towards innovation as nations have realized its importance as a major driver for economic growth and competitiveness in the market in addition to the rising awareness of sustainable development and its long-term benefits globally and in the construction sector specifically. The multidisciplinary and multi-party nature of construction projects though, necessitates a well-established framework to integrate stakeholders for achieving an effective sustainable innovation in their projects in addition to considering the different factors that influence that. This paper represents the literature that it derived its framework from. It conducts an exploratory literature review, where it investigates that literature on the aspects that are believed to be influencing stakeholder integration and the effectiveness of innovation such as open innovation and cross boundary collaboration, leadership and team identity. Then the paper proposes a conceptual framework that links the different constructs together and explains them briefly. Finally, it discusses the qualitative method that it intends to use to collect data to validate the framework in future research.

Keywords: innovation, sustainability, leadership, stakeholder integration, team identity

1. Introduction

A global shift towards innovation has been witnessed as nations have realized its importance as a major driver for economic growth and its essential role in strengthening the nations' competitiveness (Hall and Vredenburg, 2003).

The construction sector is under massive pressure to develop new practices or improve existing ones to have a less threatening effect on the environment and at the same time achieve social and economic sustainability. Although the change rate in construction is slower and the sector is considered stable, innovation became a vital source of their competitive advantage and a major element to accommodate changes in their complex products and processes (Eaton et al., 2006).

The fragmented, yet interdependent, nature of construction projects nurtured its complexity demanding a high level of coordination and integration amongst a large number of internal and external stakeholders to have an effective innovation in their projects. This becomes more vital when dealing with sustainability, which adds a new priority and more stakeholders that have different interests. A well-managed stakeholder integration process helps the different stakeholders to work together to increase comfort and quality of life by achieving sustainable innovations that decrease negative environmental impacts.

Previous studies have derived most of the conclusions about innovation implementation influencers in firms from the social science school of thought. Rogers (2003) focused on the effect of organizational climate on innovation implementation capability, West and Anderson (1996) related it to the characteristics of top management teams while Xu (2007) found a link with entrepreneurship. All of these studies are focused on the firm level and despite the increased interest in innovation at project level there is still a significant grounds to cover in this important field. Dickinson et al. (2005) shed the light on the issue at the design phase of the project and recommended more research at the project level claiming that most research tackled different aspects of innovation and stakeholder integration at the organizational level leaving some gaps when projects at involved. In addition to that and despite the number of research that has been done about innovation in the construction sector in the past twenty years, there is an obvious lack in studying the role of stakeholders in project innovation.

Rogers (2003) states that it is vital to communicate innovation through a complex social system overtime to achieve an effective innovation. He adds that stakeholder interactions and communications are usually critical factors that may affect innovation. Hall and Vredenburg (2003), Hart and Sharma (2004), and Buchel et al. (2013) agree with Rogers (2003) and considered stakeholders interaction as a major influencer. Research has also examined the impact of leadership on innovation effectiveness such as the work of Howell and Shea (2001) who studied the influence of leadership style, the characteristics and the behavior of the leader on facilitating or hindering innovation. However the link between leadership, stakeholder integration and innovation effectiveness is missing especially in the context of construction projects. This link becomes more important in the context of sustainability due to the significant role that stakeholders play in setting the sustainability agenda.
This paper, therefore, looks carefully in the literature to find the knowledge gaps and to build a framework that links the different factors to provide a clear understanding of the impact of the dynamics of stakeholder network on the success of sustainable innovations.

2. Sustainability and the need for innovation in the construction sector

Innovation is assumed to be the main driver for economic growth. It toughens the competitiveness of countries and sectors as well as individual organizations (Hall and Vredenburg, 2003). It provides a long-term profitability of firms and plays a major role in their success and continuity. However, competitiveness alone is no longer the sole driving force in the world economy. Recently, there is a predominant shift in strategy towards competitiveness and sustainability throughout the world. Competitiveness in such an economic environment is expected to be achieved through innovating products and services, processes and models that are environmentally, socially and economically viable and sustainable.

The construction sector is one of the most challenging sectors to achieve a sustainable innovation. Due to the size and importance of the construction industry to national economies and the amount of environmental damage it causes, a lot of pressure is put by nations on the sector to use more effective measures to deliver more sustainable projects, hence, the need for a shift to develop and implement sustainable innovations.

In the context of construction, innovation is defined by Slaughter (2000, p.2) as "a nontrivial improvement in a product, process, or system that is actually used and which is novel to the company developing or using it."

According to Peansupap (2004) innovations in construction can be categorized into: (1) innovation in materials, equipment and methods, (2) management innovation which are new management techniques that facilitate the process of management and administration, (3) information technology innovation refers to the electronic infrastructure and equipment which can be either software or hardware.

One of the most challenging steps to achieve sustainable innovations in the construction sector though is bringing all of the multi-disciplinary stakeholders into an agreement. Since construction projects are usually the outcome of the effort of the collaboration and coordination of multiple stakeholders, within and outside the project supply chain. Although the supply chain itself is considered the primary stakeholders of the innovation project there is no doubt the significant influence "external" stakeholders have on the innovation.

Cooper and Rousseau (1999) presented a view of the supply chain in construction projects as an 'extended enterprise' where the different parties (including project developer, architect, engineering firm, contractor, subcontractors, suppliers, regulators and users) operate as business units in collaboration representing the different functions they deliver (marketing, design, engineering, components manufacture, supply, assembly, delivery) for an entity regardless of who owns them.

In the context of construction megaprojects, it is not enough to deal with the supply chain as it is commonly and widely known; extensive intra and inter-organizational coordination is required. Recognizing changes in the competitive environment and accordingly structuring the supply chain resources to effectively meet the customers' real demands is crucial (Fawcett and Magnan, 2002).

Through conducting a survey across some innovative companies in construction, Egbu et al. (1998) found out that the organizational culture that allows flexibility in communication is a major influencer. Mitropoulos and Tatum (1999) also pointed out the culture of the organization that values innovation is important in adopting innovations. They also added that management's attitudes towards new technology and the ability of management to capture improvements to existing practices are crucial factors that influence innovation. On the other hand, Nam and Tatum (1997) noticed the importance of the role of the champions and leaders to bring out successful innovations. Blayse & Manley (2004) then identified and summarized major influencers such as the culture of the organization, the absorptive capacity, the innovation champions, knowledge codification and an innovative strategy.

Certainly, good effort from scholars is observed to enrich the body of knowledge regarding the influencers of innovation in the construction field. Nevertheless, only little research links these influencers with stakeholder management and networking techniques to facilitate innovation. Thus, more empirical studies are required in order to increase the understanding on how stakeholder integration can affect innovation in the field and how the leader play an effective role in facilitating or rendering such relationship positively or negatively.

In addition to that, it is noted that researchers unfortunately has ignored the project level and focused mainly at the firm level due to the difficulty in tracking the various activities undertaken by the heterogeneous stakeholders in the many stages of a construction project (Ozorhon, 2003; Dulaimi et al., 2002; Blayse and Manley 2004).

3. Open innovation and cross-boundary collaboration

For effective sustainable innovations in the construction sector, cross-boundary collaboration and communication and eventually the integration of stakeholders are vital.

The growth of companies in the 20th century, the increase number of knowledgeable workers and their mobility, globalization and the ease of knowledge transfer, the private venture capital market and their support for new ideas are some of the major factors that made the protection of intellectual property very difficult, Chesbrough (2003) and Heap (2010) argue.

This encouraged organizations to adopt open innovation. The idea of open innovation is not very new though it wasn't termed as such. It has been used in the construction industry continuously as the nature of the projects requires cross-boundary collaborations within the supply chain. Nevertheless, the supply chain is considered primary stakeholders, thus, the traditional way of collaborating in the supply chain ignores secondary and invisible stakeholders that can have much influence on the final innovation product and hence its performance. Therefore, open innovation strategies that are known today can overcome this issue.

The networking nature of open innovation allows for more innovation opportunities. Koschatzky claims that those who do not inter this network will have to deal with serious competitive disadvantages and may have their knowledge base reduced making it difficult to exchange relations with other organizations (in Enkel et al., 2009).

The challenge with open innovation networks is to find the right new stakeholders and learn how to deal with them in addition to motivating the internal stakeholders that forma the supply chain towards achieving the common goal of innovation. For chains that aim to deliver innovations, it is very important to align motivation in the supply chain to bring the different parties of the chain, which have different interests, into a mutual agreement to ensure the successful development and implementation of the innovation.

Hall and Vredenburg (2003) discussed the ambiguous and complex impact of secondary stakeholders on the attempt to achieve innovations and stressed that it is of extreme importance to consider them while initiating the innovation process. Hall and Vredenburg (2003) and Hart and Sharma (2004) argue that the traditional ways of innovation focus only on a narrow range of stakeholders; thus, unexpected rejections and hindering will be faced when attempting to deliver the innovation. They also stressed on the fact that dealing with a wide range of important yet, invisible, stakeholders in this case is very crucial.

Once the stakeholders are clearly defined and identified, they can be integrated to create positive collaborative relationships among each other for the benefit of the innovation (Sharma and Vredenburg, 1998).

4. Leadership for sustainable innovation

Leadership reflects the goal-directed influence that one person has over other members of an organization or a group in guiding, structuring, facilitating relationships and activities. Thus, the role of the leader is key for the project to function in an effective and innovative manner (Nam and Tatum, 1997). It is the leader's role and power to introduce new ideas, goals and innovations in projects; therefore, leadership style is considered a crucial attribute in influencing innovation (Bossink, 2004).
Transformational leadership (Jung et al., 2003), innovation championing (Howell and Higgins, 1990), leader-member exchange (Graen and Uhl-Bien, 1995) are the major leadership styles that have been identified to have a positive influence on innovation.

Many researchers have linked transformational leadership to innovation such as Howell and Avolio (1993) and Jung et al. (2003). According to Jung et al. (2003) this leadership style is the preferred style to enhance innovation; they introduce creativity and innovation by actively engaging followers' and stakeholders and link their identities to the collective identity of their organization, thus raising their intrinsic motivation rather than just providing them with extrinsic motivation to perform their tasks. Through the development of important vision and mission, transformational leaders raise the followers' understanding of the value of the desired outcome, thus raise their performance and their willingness to exceed their self-interests for the sake of the organization (Howell and Avolio, 1993). This type of leadership also promotes collaboration by stimulating collective goals, building trust, empowering people, developing competence and offering visible support (Jung et al. 2003).

Leader-member exchange style suggests that innovativeness has a direct relationship with the relationship between the leader and the followers (Scott and Bruce 1994). It relies on the effectiveness of developing mature partnerships based on trust and support. This leads the employees and stakeholders to risks and deviate from the status quo (Scott and Bruce, 1994).

The last leadership style is the championing behavior. Rogers (2003) claims that a leader with an innovation champion personality have a direct influence on innovation diffusion. The presence of an innovation champion has been widely related to the success of innovations (Howell and Higgin, 1990; Howell and Shea, 2001; Nam and Tatum, 1997).

Champions have the power to affect the internal distribution of power and resources, strategic actions, and performance either positively or negatively. In addition, they can determine some internal organizational consequences such as the speed and position of career progression and the motivation or retention of members. On the cross-functional level, champions can promote communication between stakeholders and facilitate effective decisions about the innovation projects (Howell and Shea, 2001).

These different leadership characteristics have different influences on the ability to integrate stakeholders to achieve the ultimate goal of innovation. This study will investigate this further keeping in mind that the leader can be a person in the innovation project or the entire management team of the project.

So, through literature, leadership has an influence on stakeholder integration, and stakeholder integration facilitates the effective development and implementation of the innovation. However, these are general findings and the dynamics that actually take place in the project are missing in the literature. How can stakeholder integration influence the innovation? What happens in the innovation team if stakeholders are integrated? What are the dynamics that take place at the project level?

5. Innovation team identity

Unlike innovation at the organizational level, where the norms, roles, tasks of members are defined by the corporate law, corporate governance and the formal organizational structure (Child, 1972); innovation at the project level defines the tasks and roles of members through informal rules that the team adopt to regulate team members behavior gradually (Rese and Baier, 2012). In this case, the norms that define team members' behavior are highly dependent of the interactions among them and are related to the group identity (Postmes and Spears, 2000).

Rese and Baier (2012) argue that it is vital for the innovation team members to develop a specific self-concept as a team, which reflects the identity of that team. Here comes the significant role of the leader as discussed previously where the different styles of leadership enhance this behavior in different ways.

The formation of team identity is explained by social identity theory developed by Tajfel and Turner (1979). They claim that group identity is the feeling of belonging o individuals to certain groups that create some emotional and value significance to them and a sense of membership.

Team identity develops when team members interact with each other. Rese and Baier (2012) encourage the close communication of the project's team members to achieve a common understanding of the innovation project. Interacting behaviors of the team members are either presented in tasks or in socio-emotional behaviors.

The membership to a specific team is determined by group boundaries. Boundary is an important issue in construction projects as the team members are assigned to different organizations and they interact with different groups. Being aware of the goal of innovations and having a clear definition of the goal makes them in risk of having a conflict of interest with the goals of the organization that they originally come from and they might face significant opposition in this situation which leads to substantial conflicts. Thus, shedding the light of how to manage this for the favor of the innovation project is very crucial Rese & Baier 2012.

Friedlander (1987) identifies some dimensions that affect the quality of group boundaries: boundary clarity and permeability, the degree of cohesion between group members, the degree of match between group members' functional identity and local language, and the climate within the team (in Rese & Baier 2012).

Boundary clarity is the degree to which the innovation team is independent of other teams (Rese & Baier 2012). Teams that work on projects are less structured than organizational teams, thus, they need to deal with more uncertainty and ambiguity necessitating additional clarity. This assists in strengthening team membership, thus their commitment to the common goal.

Boundary permeability on the other hand deals with information flow and the circumstances that can hinder or facilitate the inward and outward flow of communication (Alderfer 1977; Agazarian 1989). Ellemers et al. (1988) claim that the more permeable the boundary is, the stronger identity the team can have.
Cohesion is another important dimension that can affect the identity of the team. According to Festinger et al. (1950), cohesion is the desire of the innovation team members to remain in the team and to commit energy and resources to the common innovation project. This element is very important and is very much related to the development of a common understanding by pursuing common goals and tasks, which results in facilitating team identity and membership.

The last element that increases membership of the team members and consequently strengthens their identity in the innovation project is the shared perceptions of the team's policies, practices, and procedures (Reichers and Schneider, 1990) promoting innovation, cooperation, and mutual support.
These elements have been empirically proven to increase innovation project performance (Rese and Baier, 2012) and are influenced by the leadership style as discussed earlier.

6. Conceptual framework

From the literature, there are different factors that influence innovation effectiveness, however, the concepts are fragmented and not linked to give an overall picture of the dynamics that take place at the project level. Hence, this research establishes the missing links through the following framework (Figure 1). The framework suggests that in an open innovation context, leadership influence stakeholder integration, which results in decreasing ambiguity and giving a clear definition of project's goals. Having that leads to establishing a strong team identity that have a passion and dedication towards the innovation thus increasing the chance of having a successful and effective innovation.

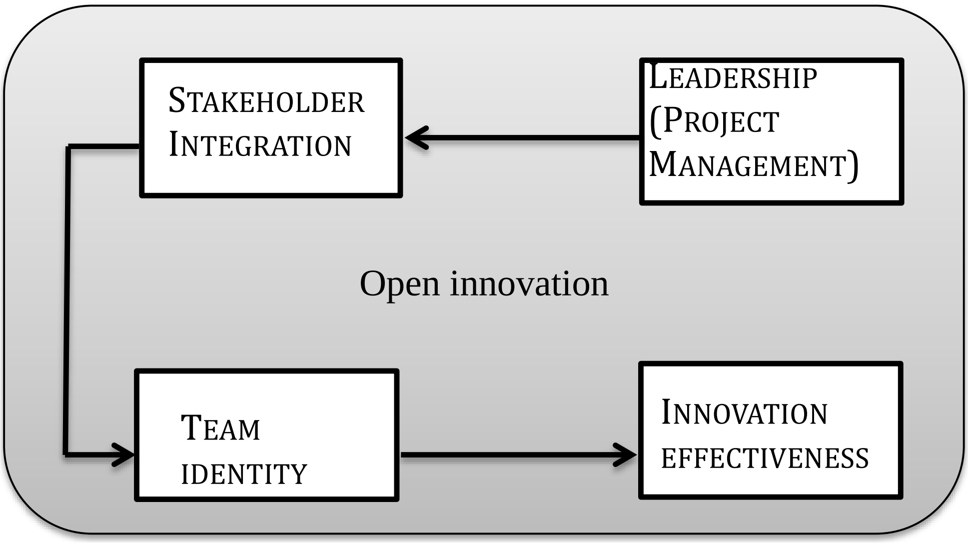

Figure 1: Framework

Each of these constructs are explained below:

Open innovation is the use of purposive inflows and outflows of knowledge to accelerate internal innovation and expand the markets for external use of innovation, respectively (Chesbrough 2006, p. 2)

Leadership the goal-directed influence that one person has over other members of an organization or a group in guiding, structuring, facilitating relationships and activities ((Nam and Tatum, 1997).

Stakeholder integration is the ability to create positive collaborative relationships with a wide range of stakeholders (Sharma and Vredenburg 1998).

Team identity is the feeling of belonging of individuals that create some emotional and value significance to them and a sense of membership (Tajaful and Turner 1979).

Innovation effectiveness is the overall project's outcome that results from implementing the innovation. In this study's context: it is financial, social and environmental effectiveness, which arises specifically from implementing the innovations.

The following table shows the measures that are used to assess each construct based on the existing literature:

Table 1: Measures of the study constructs

Construct	Construct	Measures

number	name	
1	Open innovation	• Co-creation with partners • Alliances • Joint ventures • Cooperation • Customer involvement • Employee involvement • Social network • Spin offs • Selling IP
2	Leadership	• Championing: - Internal distribution of power, resources, strategic actions, performance. - Communication with stakeholders. • Leader-member exchange - The effectiveness of developing mature partnerships based on trust and support. - Leads employees and stakeholders to risks. • Transformational leadership - Introducing creativity and innovation by actively engaging followers and stakeholders and links their identity to the collective identity of the project. - Empowering people. - Building trust. - Developing competence. - Offering visible support
3	Stakeholder integration	• Cooptation - Dealing with direct stakeholders that vary in salience. • Buffering - Close links with representative organizations to avoid dealing with unnecessary people. • Meta problem solving - Networking • Mutual learning - Mutual dependence between unlike organizations managed by processed adaptations.
4	Team identity	As a team: • Cohesion • Boundary clarity • Degree of match • Local language • Climate • Permeability As individuals: • Self categorization • Evaluation • Importance • Attachment

		• Social embeddedness • Cognitive awareness • Behavioral involvement
5	Innovation effectiveness	• Financial • Social • Environmental

This framework will be used to guide the next stage of the research that involve a deeper analysis through the production of case studies and interviews with key parties in selected case studies that are involved in sustainable developments. It will promote for open innovation and knowledge sharing and cross-boundary learning. Although it studies the concepts at a project level, it gives insights on how managing integration can lead to a better management of sustainable innovations in general. In specific, it will aid in understanding how the dynamics of stakeholders play a role in the team behavior towards achieving the sustainability goals of their projects and at the same time understand the role of the leader in steering stakeholders towards supporting the projects goal through a better integration.

7. Conclusion

This paper intended to build a conceptual model that explains the effect of stakeholder integration on innovation effectiveness in sustainable construction projects. The researcher investigated the theory and literature on the subject of stakeholder integration in the construction field and proposed direct and dynamic links with open innovation, leadership and team identity. These links are believed to have direct and indirect influences on the effectiveness of innovation.

Due to the multiplicity of stakeholders and their various interests, powers and urgencies in construction projects, they have a direct influence on innovation. Unfortunately, through a thorough literature investigation, empirical studies that investigate the influence of stakeholder networks and their integration in the construction project are very scarce and usually cover how the culture and climate of the organization play a role in integrating stakeholders. This leads to missing some important aspects that can be addressed in order to foster innovation through a better integration mechanism that supports open innovation in construction projects.

This research will promote for open innovation to achieve sustainable development and knowledge sharing and cross-boundary learning. Although it studies the concepts at a project level, it gives insights on how managing stakeholder integration can lead to a better management of innovations in general. In specific, it will add to the construction projects as the conceptual framework that will be developed and thoroughly validated will be applicable in projects that seek to diagnose the condition of their innovative practices. It will also offer many implications that can guide firms to strategize innovation and ultimately improve their business performance.

The Impact of Client Involvement on Project Performance: Case of the Kingdom of Saudi Arabia

Bambang Trigunarsyah[1] and Sultan Al Solaiman[2]

Email: bambangts@kfupm.edu.sa

Abstract

The construction sector in Saudi Arabia is the largest and fastest growing market in the Gulf region. This strong economic position has encouraged the Saudi Government to take the opportunity to implement spending and launch many construction projects. However, a United Nations Development Programme Report indicated that Saudi Arabia was not progressing well in implementing effective management and achieving good organisational performance. This was clearly demonstrated by the number of projects suffering delay, which increased from 700 projects in 2009 to 3000 projects in 2013. The lack of client involvement in the construction of public projects has been identified as the main cause of many operational problems such as cost and time overruns, disputes, errors, uncertainties in plans and specifications, and increased maintenance costs. This paper investigates client's involvement in construction project delivery and its impact to project performances. A questionnaire survey was distributed to various government agencies of the Kingdom of Saudi Arabia (KSA). Descriptive statistical analyses were used to assess the current practices of clients' involvement and its impact to project performances. The relatively low client involvement has a negative impact on the projects' ultimate outcomes. This condition has negatively affected the time completion of construction projects in Saudi. It was also indicated as the main cause of quality problems in Saudi's construction project.

Keywords: client involvement, project performance, Saudi Arabia

1. Introduction

The construction sector in Saudi Arabia is the largest and fastest growing market in the Gulf region (Samargandi et al., 2013). This strong economic standing has encouraged the Saudi Government to take the opportunity to spend money on many projects. In the last five years, Saudi Arabia has experienced a construction boom with over 16,500 ongoing public projects and a total value equal to US$956 billion (Ministry of Finance, 2012). However, a United Nations Development Programme Report indicated that Saudi Arabia was failing to make real progress in achieving good management and organisational performance (United Nations

Development Programme, 2009). This was clearly demonstrated in the number of projects experiencing delay, which increased from 700 projects in 2009 (Althynian, 2010) to 3000 projects in 2013 (Anti-Corruption Commission, 2013).

Construction project management practices in Saudi Arabia are varied (Bubshait and Al-Musaid, 1992) due to the different nationalities of the construction industry professionals. Furthermore, the quality of public projects has varied among government agencies due to the different approaches used. Some examples of problems experienced in construction projects in Saudi Arabia include cost and time overruns, disputes, errors, uncertainties in plans and specifications, and increased maintenance costs. The lack of client involvement in public construction projects has been proposed as the main cause of myriad problems (Althynian, 2010).

This paper investigates client's involvement in construction project delivery and its impact to project performances. The paper starts with a literature section, which briefly discuss the construction sector in Saudi Arabia and the important of client involvement in delivery construction projects. It is then followed by describing the research method that was selected to achieve the aim of the paper. Results of the analysis are then presented in the subsequent section, followed by the discussion of the findings. The paper is concluded by presenting the key findings of the study.

2. Literature Review

2.1 Construction Sector in Saudi Arabia

The varying degrees of client involvement in public construction projects has been identified as a reason for the various levels of quality achieved in different construction agencies in the Kingdom of Saudi Arabia (Bubshait, 1994, MEED, 2010). In the relationship between the parties in Saudi projects, the consultant has traditionally been considered as the major player in the construction project, and this approach has served to isolate the contractors from the client (Kometa et al., 1996). This isolation reduces the client's influence on the project and makes the client dependent on the consultant (Assaf and Al-Hejji, 2006). Furthermore, there is a perception among the clients in government projects in Saudi Arabia that the consultants are often correct, even if their recommended resolution is different from the client's preference (Alnuaimi et al., 2009).

Construction projects in Saudi Arabia experience major delays (Al-Kharashi and Skitmore, 2009). Some studies have been carried out on the causes of these delays in Saudi construction projects. Assaf et al. (1995) found that the most important causes of delay were related to client involvement in project processes such as involvement in planning and design, and slow responses when making decisions and granting approvals for materials. Al-Barak (1993) found that the causes of failure in some construction projects in Saudi Arabia were related to the clients' lack of experience and weak involvement in project activities. Assaf and Al-Hejji (2006) found that delays in construction projects originated mostly in client-related factors. Al-

Khalil and Al-Ghafly (1999) found that slow decision outcomes by the client were a major cause of project delay in Saudi Arabia. It appears that the problems experienced in construction projects in Saudi Arabia are mainly caused by the low level of client involvement during project activities. The weak decisions in the early stage of a project will result in a conflict between all parties in the later stages. Therefore, client involvement during the formative and early design stages of a project is a critical factor that must be taken into account if a project is to be delivered on time, to budget and to the desired quality (Love et al., 1998).

2.2 Client Involvement in Construction Projects

A successfully constructed project begins with the client (Ryd, 2004). Clients who are closely involved in managing a project are usually the most satisfied with the project quality (Bubshait and Al-Musaid, 1992). However, the client has duties and responsibilities when involved in the construction process. Clients should identify and adopt effective practices that contribute to high performance in their involvement in the construction process (Al-Kharashi and Skitmore, 2009).

Involvement is determined by the degree to which the project team fulfils its responsibilities to each phase of the total construction process (Bubshait, 1994). Clients need to perform their duties and responsibilities to have the optimum involvement required during the construction project phases, namely, the planning phase, design phase, construction phase, handover phase, and operation and maintenance phase. The degree of client involvement is based on taking the right decision during the construction project processes. Generally, client involvement procedure is based on the weight of the client's experience (Nutt, 2006). Therefore, for many construction projects, making good and timely decisions is not an easy task to accomplish.

Client has three common expectations for the project delivery: high quality, low cost; and finished on time (Forgues, 2006). Client's objective is to get the balance right between all these elements in order to meet the client's project delivery expectation. The importance of the client role was highlighted in the ASCE Quality in the Constructed Project Manual (ASCE, 2012). The manual describes the high impact that the client has on the construction project, which in many cases may determine the project's success or failure. Therefore, the clients' involvement in the early stages constitutes an initial phase of the construction process and provides the link between the client and the project (Institution of Civil Engineering, 1996).

3. Research Method

For this study, a questionnaire survey was selected as the research method. The development of the questionnaire followed Leedy (1997) four practical guidelines, which are: using clear language, meeting research aims, planning development including distribution and collection, and creating a solid cover letter. The survey was written in two languages (English and Arabic) which are appropriate for the participants. Close-ended questions with ordinal and nominal scales were employed. Instructions were also provided at the beginning of each section for completing the questionnaire.

The questionnaire consisted of three main parts. Part 1 was designed to obtain some demographic information about the participants. Part 2 was designed to identify the degree of client involvement in construction projects. Part 3 was designed to identify the impact of the current client involvement practices on the delivery of construction projects in Saudi Arabia.

A pilot survey was conducted in order to identify any further need of revision. A sample of 9 respondents was selected to complete the survey to test the content validity of the questionnaire items. The questionnaires were distributed in both languages (Arabic and English) based on the preference of the participant. Email and post were used to distribute the questionnaires

4. Results

The questionnaire survey was distributed to 315 potential participants in 21 government agencies of the Kingdom of Saudi Arabia (KSA). 17 of the 21 (80.95%) agencies responded, with a total of 223 questionnaires (70.79%) were returned, giving the researcher more precision and more confidence in regard to understanding the sample population. Among the respondents, 42.6% worked in public agencies and 57.4% worked in semi-public agencies. The project types that the respondents built include: building; infrastructure; industrial; and other.

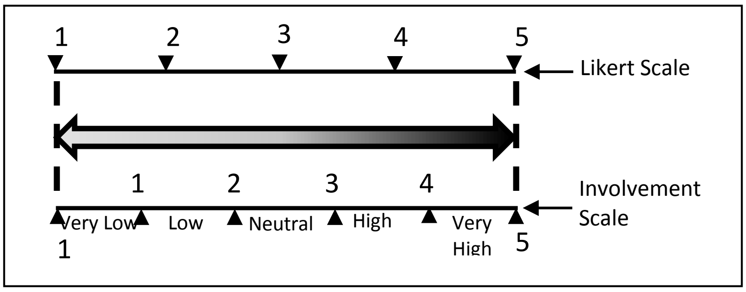

Figure 1: Likert and involvement scale profile used for Part 2 in the questionnaire

Descriptive statistics for the respondents' involvement as clients were produced, using the mean as the measure of central tendency. Although the median would theoretically be a more accurate measure because the data were ordinal, the mean was used due to the nature of the data. To locate the level of involvement, the "involvement scale" was developed in five intervals: "very low", "low", "neutral", "high" and "very high". The involvement scale was calculated by dividing the four intervals in the Likert scale by the five involvement intervals. The result was

0.8 for each interval. Therefore, the "involvement scale profile" was built based on the five-point Likert scale (Figure 1). Skewness and Kurtosis test was conducted for normality distribution. The Cronbach's alpha test was used to evaluate the consistency and reliability of he questionnaire.

Table 1 presents the results on the respondents' level of involvement as clients in the planning phase. The average level of client involvement was considered low, ie 2.07(Figure 1). The planning phase in a construction project is normally executed by the client. In this study, the planning phase was represented through 11 tasks.

Table 1: Mean ranking of client involvement in planning phase

Code	Planning Phase Activities (Tasks)	Rank	Mean
Part2_A_6	Approval of the project cost	1	1.54
Part2_A_11	Feasibility study of the proposed project	2	1.61
Part2_A_10	Description of the responsibilities and powers of each member	3	1.72
Part2_A_4	participating in the project	4	1.86
Part2_A_8	Studying how to secure funds to finance the project	5	1.94
Part2_A_9	Studying the impact of the project on health and safety	6	2.04
Part2_A_5	Establishment of a criterion for the selection of project location	7	2.11
Part2_A_1	Estimation of the project cost and the time required for its completion	8	2.21
Part2_A_2	Assignment of task force (consultant, engineer etc.) to conduct	9	2.50
Part2_A_3	preliminary studies for the proposed project	10	2.58
Part2_A_7	Studying the requirements of the beneficiary of the project	11	2.68

The respondents' level of involvement as clients in the planning phase tasks was varied but low across all the tasks; involvement in three tasks was ranked as very low (scale 1 to 1.8); involvement in seven tasks was ranked as low (scale 1.8 to 2.6); and involvement in one task was ranked as neutral (scale 2.6 to 3.4).

The design phase was represented through 11 tasks. Table 2 presents the results on the respondents' level of involvement as clients in the 11 tasks in the design phase. The respondents' level of involvement was higher in the design phase than in the planning phase. The average client involvement in design phase was 2.64, which is considered to be neutral involvement based on the involvement scale profile (Figure 1). Clients and designers usually work together during this phase. The level of involvement was low or neutral across all the tasks: involvement in five tasks was ranked low (scale 1.8 to 2.6) and involvement in six tasks was ranked neutral (scale 2.6 to 3.4).

Table 2: Mean ranking of client involvement in design phase

Code	Planning Phase Activities (Tasks)	Rank	Mean
Part2_B_4	Negotiating design price with the qualified designers	1	2.04
Part2_B_3	Selection of design team	2	2.07
Part2_B_7	Evaluation of design and taking the necessary decisions	3	2.47
Part2_B_10	Update drawings and specifications to reflect the requirements of location or environment	4	2.54
Part2_B_1	Arranging the papers and documents of the construction contract	5	2.57
Part2_B_5	Provide the designers with the necessary information for the project	6	2.70
Part2_B_2	Qualification of designers bidding on the project	7	2.74
Part2_B_11	Use of some technical standards for the descriptions of material quality or construction methods to be followed during the project	8	2.80
Part2_B_9	Monitor and guarantee design quality	9	2.93
Part2_B_6	Following the progress of design	10	2.97
Part2_B_8	Review of design documents (e.g., drawings and specifications)	11	3.19

Table 3: Mean ranking of client involvement in construction phase

Code	Planning Phase Activities (Tasks)	Rank	Mean
Part2_C_3	Negotiating contract price with the contractors qualified to do the job	1	1.67
Part2_C_1	Qualification of contractors competing to implement the project	2	2.49
Part2_C_4	Interpretation and clarification of ambiguities in the contract documents and drawings	3	2.50
Part2_C_2	Explaining the objective of the project and providing the necessary information for bidding	4	2.60
Part2_C_5	Review the documents that submitted by the contractor	5	2.85
Part2_C_9	Establishment of a system and written code to ensure implementation quality, to be referred to by personnel in charge of implementation quality assurance and control	6	2.96
Part2_C_10	Emphasis on implementation quality by conducting necessary tests for the various implementation stages	7	2.99
Part2_C_6	Taking necessary decisions against contractor claims during project implementation	8	3.26
Part2_C_11	Regularly visit project site during implementation stage	9	3.31
Part2_C_8	Stress implementation quality and monitoring safety principles during project implementation	10	3.53
Part2_C_7	Monitoring and control of implementation methods and cost, as well as work schedule and contractor productivity	11	3.60

The construction phase was represented through 11 tasks. Table 3 presents the results on the respondents' level of involvement in the 11 tasks in the construction phase. The respondents' level of involvement as clients in the construction phase was ranked as the second highest level of involvement across all the project phases (following the handover phase). The average client involvement in the construction phase was 2.89. The level of involvement across the tasks was varied: involvement in one task was ranked as low (scale 1 to 1.8); involvement in three tasks was ranked as a low (scale 1.8 to 2.6); involvement in five tasks was ranked as neutral (scale 2.6 to 3.4); and involvement of two tasks was ranked as high (scale 3.4 to 4.2).

The respondents' involvement as clients was the highest in the handover phase among all the phases. The average client involvement in the construction phase was 3.19, which is considered to be neutral involvement but close to high involvement based on the involvement scale profile. The handover phase was represented through three tasks. Table 4 presents the results on the respondents' involvement as clients in the three tasks in the handover phase.

Table 4: Mean ranking of client involvement in handover phase

Code	Planning Phase Activities (Tasks)	Rank	Mean
Part2_D_1	Establishment of criteria for acceptance of completed project	1	3.09
Part2_D_3	Monitoring the process of testing and commissioning	2	3.11
Part2_D_2	Review of contract documents after completion of the project	3	3.36

The respondents' level of involvement in the operations and maintenance phase was the lowest amongst all the phases. The average client involvement in the O&M phase was 2.06, which is considered low involvement based on the involvement scale profile (Figure 1). Table 5 presents the results on the respondents' level of involvement as clients in the O&M phase.

Table 5: Mean ranking of client involvement in O&M phase

Code	Planning Phase Activities (Tasks)	Rank	Mean
Part2_E_1	Prepare the maintenance plan describing the maintenance schedules and lists the tasks	1	1.93
Part2_E_4	Building up the inventory including the important spare parts to maintain and operate the project with minimum "down time"	2	1.98
Part2_E_2	Prepare the operation information such as to assist in solving problems and prevent unexpected expensive	3	2.09
Part2_E_3	Record the warranties and certificates reference information	4	2.24

The respondents were asked, "To what extent were the projects implemented" in relation to the following goals and expectations: (1) time, (2) cost, (3) quality, and (4) operational satisfaction. Table 6 presents the results on the respondents' level of agreement in term of the impact on the client involvement on project delivery.

Table 6: Impact on project delivery

Code	Project Objectives	Mean	Std. deviation
Part3_1	Time	1.87	.678
Part3_2	Cost	2.84	.793
Part3_3	Quality	3.09	1.083
Part3_4	Operation	3.14	1.203

For more understanding of the impacts of client involvement, this impact was investigated in three ways, which are based on: (1) the overall data; (2) organisational type (public or semi-public); and (3) project type (building, infrastructure, industrial, and other). Figure 2 presents a summary of the results.

As shown in the neutral and negative impacts depicted in Figure 2, the respondents reported that projects were implemented with time delays, higher costs than contracted, the typical quality was not high, and operations were slightly satisfactory. This indicates that a low level of involvement during the construction project phases (as presented in Table 1 to 5) has a negative impact on the end of the project regarding the desired goals of high quality, low cost, on-time completion, and no major disruptions in operations.

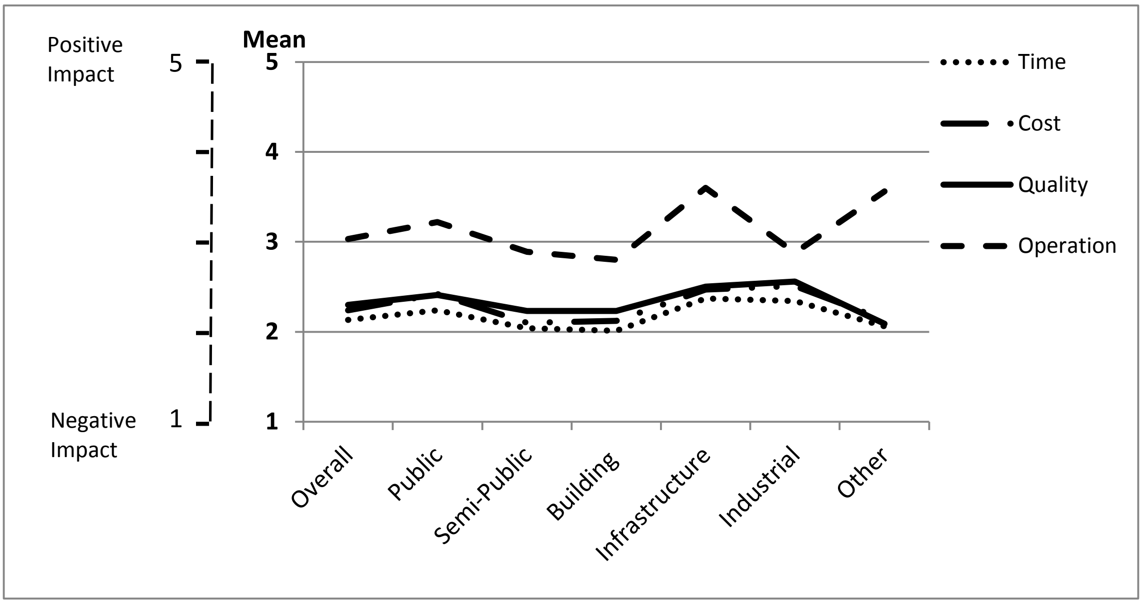

Figure 2: Impact of client involvement on project implementation

5. Discussion

As identified in this study, the construction project process has five phases with 40 tasks that measure most activities during the construction project cycle. The survey revealed that clients had inadequate involvement in 38 out of 40 tasks in the construction project phases. This low level of involvement is very likely to have a negative impact on the project outcomes.

In the planning phase, the average client involvement was 2.07 on the involvement scale, which is considered low. The levels of client involvement in "Approval of the project cost", "Doing feasibility study of the proposed project", and "Describing the responsibilities and powers of each member participating in the project" were very low. These three tasks are highlighted as an example to illustrate the importance of the planning tasks. The planning phase includes activities that require a high level of authority to make decision, such as "Approval of the project cost". In any large project in Saudi Arabia, government agencies require formal approval from the Ministry of Finance before awarding the contract (Government Tenders and Procurement Law, 2006). The restrictions imposed by the Ministry of Finance for approval of a project reduce the ability of clients to innovate in construction due to limitations in the project budget. Therefore, according to the specialist in budget, the budgetary and financial management system in Saudi Arabia needs to reform and change (Albassam, 2011).

Another important activity in the planning phase is "Undertaking the project feasibility study" which is an analysis of the ability to complete a project successfully, taking into account legal, economic, technological, scheduling and other factors. The consequences of not doing the feasibility study correctly may be sufficient to stop the project. The risk of this consequence was evident in the low client involvement in this task. Low client involvement in the planning phase may account for the dramatic increase in the number of project delays in Saudi Arabia in the last three years (Anti-Corruption Commission, 2013).

While the planning phase is important for making the right decisions to start the project, the design phase is no less important for the project. Eighty percent of a project can be specified at this phase (Whelton et al., 2002). In this study, the average client involvement in the design phase was 2.64 on the involvement scale which is considered neutral involvement. Clients need to have advanced knowledge to be able to review the design documents. It is recognised that more involvement by project client in the early design stage has a positive impact on delivering the construction project successfully.

It is important to recognise the close relationship between the design and construction phases. The design phase is a process of creating the description of a new project, usually represented by detailed plans and specifications, while the construction phase is a process of identifying the activities and resources required to make the design a physical reality. Clarification in design documents leads to less conflict between the client and contractor (Al-Sedairy, 1994). This study found that clients did not pay enough attention to the tasks that need to be implemented well before constructing the project during the tender selection process. These tasks are "Negotiating the contract price with the contractors qualified to do the job", "Checking the qualification of contractors competing to implement the project", "Interpretation and clarification of ambiguities in the contract documents and drawings", and "Explaining the objective of the project and providing the necessary information for bidding" as presented in Table 3. Lack of attention to these tasks might result in conflict in the construction project. These conflicts occur most frequently in the key relationships of the contractor and the client, and the contractor and the consultant. Research has found that the conflict was likely to occur most strongly in the later stages of a project under construction (Althynian, 2010). Therefore, it is important to emphasise that the client needs to be pay more attention to the design and construction phases.

The handover of the project to the client at the end of the construction is a very important stage of the project procurement process and facility operation success. Reflecting the importance of the handover phase, the level of client involvement in handover tasks was found to be near a high level of involvement. A well-organised, efficient and effective transfer of information from project contractors to the owner of the project is essential. The commissioning and fine-tuning of operations during handover can impact heavily on the use of the project if not managed in a structured manner.

At the end of a project, project satisfaction is measured during the operations and maintenance. However, in this study, the level of client involvement was found to be the lowest amongst all the project phases. Successful operations and maintenance of a completed project is closely associated with the level of client involvement. Therefore, the project team benefits by giving careful consideration to the operational and maintenance objectives during the project's planning, design and construction stages. One suggestion for clients to consider during the construction process is to assign a special O&M representative to advise the project team on how to complete the product in a manner that best achieves the project's O&M needs.

6. Conclusions

The construction sector in Saudi Arabia is the largest, strongest and fastest growing market in the Gulf region; however, the construction sector in Saudi Arabia has faced many challenges during the recent construction boom. These challenges include the lack of real progress in achieving good management and organisational performance, variability in quality among the projects commissioned by government agencies, increasing project delays and cost and time overruns, lack of planning and design, and weak supervision by the government agencies of the construction project process.

The findings from this study show that the current client involvement in construction projects in Saudi Arabia is at the level of neutral or low involvement. Among the five project phases of the construction process, the design phase was ranked as the priority phase for client involvement during the construction project. This is then followed by the client involvement in the planning phase. However, the study found that the respondents had low involvement as clients in both the planning and the design phases. This was suggested as the reason of weak decision-making in the early stage of the project, which could result on conflict in the later stages of the projects. The remaining phases were ranked in importance as follows: (3) construction phase; (4) handover phase; (5) operations and maintenance phase. The relatively low client involvement has a negative impact on the projects' ultimate outcomes. This condition has negatively affected the time completion of construction projects in the Kingdom of Saudi Arabia. It was also indicated as the main cause of quality problems in Saudi's construction project.

The Role of Product and Service Innovations in the Finnish Construction Industry

Kai Hänninen[1], Krishna Chauhan[2] and Harri Haapasalo[2]

Abstract

Indent to succeed, the construction industry must offer quality products and services that are in line with customer demands. The objective of this study was to describe the role of product and service innovation in the Finnish construction industry by sectors. This study was qualitative in nature. Research followed a two-fold process: 1) analysis of Finnish construction patent data, provided by the Finnish Patent and Registration Office (PRH), and 2) a case study. The purpose of this research was to explore patenting activity in different construction sectors and its relation to product and service innovation within construction companies.

Our results indicate that patents have a significant role in the construction product sector. The building sector is also innovative, but generally in organisational structure and market innovations rather than in product or service innovations.

The role of development activities in Finnish construction industries is complex. Innovation seems to be quite straightforward in the construction product sector because these companies are seeking to produce the 'right' products. The issue of innovation is more complicated in other construction sectors. Even the definition of what a 'product' is varies among building construction companies. As a result, the products offered to customers might be inappropriate or ineffective in meeting customer requirements. On the other hand, the provision of services has become a more important part of many companies' operations.

The construction industry faces problems and challenges in many operational areas. Earlier studies have claimed that building construction is a very conservative field in the industry. The results of this study bear out this idea. The study provides support for managers considering development activities as a solution to better serve customers and increase innovativeness within the organisation. Innovation has a significant effect on a nation's economy and competitiveness by expanding employment opportunities, increasing economic growth and improving the standard of living.

Keywords: Patents; Innovation; Process; Development; New products and services

1. Introduction

How does the construction industry understand development and its benefits? The construction industry is usually not considered innovative compared with other industries (Sexton and Barret, 2003; Winch, 2003). In fact, the building construction sector is sometimes accused of being backward and stuck in the 19th century. While other lines of business have been able to increase their productivity, quality and value, the construction industry has suffered from a lack of innovation (Winch, 2003).

The competitive advantage of an enterprise depends on its ability to create more value than its rivals (Porter, 1985; Brandenburger and Stuart, 1996). Industrial innovation includes not only radical innovations but also incremental technological advances (Trott, 2012). High levels of innovation embedded in products, services and processes increase the possibility for growth and profits (Pleatsikas and Teece, 2001; Sattler, 2003). According to Trott (2012), innovations can be divided into seven typologies: 1) product, 2) process, 3) organisational, 4) management, 5) production, 6) commercial/marketing and 7) service.

In most countries, the construction industry is known to be a slow adopter of new processes and technology, which hampers the innovation process (Wandahl et al., 2011). Many researchers argue that the whole construction sector (including manufacturers of building products and systems, designers and property managers) makes up about 15% of the gross national product of most nations (Marceau et al., 1999; Seaden and Manseau, 2001). Achievement of innovation and development and the drivers of and barriers to development are comprehensively interrelated with the features and evolution of the industry (Pavitt, 1984; Malerba, 2004).

In current markets, new product development and innovation are essential for value creation (Hurmelinna-Laukkanen et al., 2008). New product development in today's business environment is challenging because of short product lifecycles, technical complexity, market uncertainties and rising costs of development (Bhaskaran and Krishnan, 2009; Cooper et al., 2001). To succeed competitively, enterprises need to offer products and services that meet the various needs of customers and the marketplace (Ulrich and Eppinger, 2011). The framework of development is about defining, designing and developing new products or services for the product portfolio (Ulrich and Eppinger, 2011; Cooper, 2001).

The construction industry is generally thought of as a large, dynamic and complex industrial sector which plays an important role in a country's economy. However, the industry is commonly criticized for being non-innovative and conservative (Bygballe and Ingemansson, 2014). This underlines the crucial need for such an economically important industry to become more innovative, specifically in the area of product development. A major objective is the designing of products in response to customer demand. In general, buildings are known as the main products of the construction industry, and the industry has put much effort into implementation of new production and procurement philosophies (Ozorhon et al., 2009). Yet, the construction industry, by nature, has many unique problems, and the importance of taking measures to improve the performance of the industry has now been recognised in several countries at various levels of socio-economic development (Ofori, 2000). According to Kajander et al. (2012), the top management of companies operating in the construction sector recognise that sustainability innovations are relevant to business development. This study aimed to answer the following research questions:

RQ1: What is the role of Finnish construction patent creation in different sectors?

RQ2. What is the role of product and service innovations in the Finnish construction industry?

2. Method

The research process was divided into five phases: study design, data collection, data analysis, results and conclusion. First, background research was conducted to obtain an adequate outline for the analysis of the role of development in the construction industry. A two-part data collection phase followed: 1) a construction patent data report from 2004 through 2014 was ordered from the Finnish Patent and Registration Office (PRH) and 2) a semi-structured interview questionnaire was developed, and company representatives were selected for interviews. Company representatives were interviewed to clarify current managerial level practices of development. The patent and interview data were then analysed, and conclusions were made. The research process for this study is presented in Figure 1.

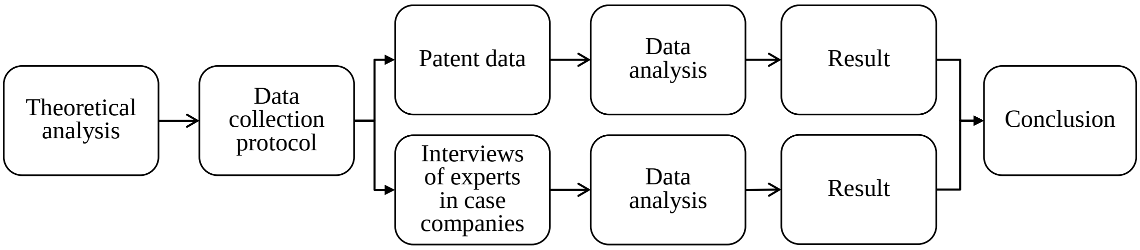

Figure 1. Research process

Qualitative research refers to any type of research that produces findings not resulting from statistical or other means of quantification (Corbin and Strauss, 2007). However, multiple data collection techniques can be employed in case studies and are likely to be used in combination with one another (Saunders et al., 2007, p.139). Moreover, both qualitative and quantitative evidence can be collected in a case study (Yin, 2003); in fact, Yin (2003) encourages using both techniques. In line with Yin's (2003) guidelines, a combination of qualitative and quantitative evidence was collected in this study. However, the main focus was on qualitative analysis.

Construction industry patent data from 2004 to 2014 was ordered from the PRH. Analysis of Finnish patent data according to the construction sectors defined by the Confederation of Finnish Construction Industries (CFCI) required the creation of a mapping table that included PRH classifications, CFCI sectors and International Patent Classifications (IPC) (see Appendix, Table 4). The CFCI's five sectors are 1) building construction, 2) construction products, 3) infrastructure, 4) heating, plumbing and air-conditioning (HPAC) contractors and 5) surface contractors.

The interviews were conducted with six companies (see Table 1). The number of cases was limited to six in order to achieve an in-depth understanding of the phenomenon studied. These companies were able to offer comprehensive study material relevant to the phenomenon, including information about products and/or services, business models, development projects, factors contributing to the development process and factors making development difficult. Topics that were company specific are not reported. The selected participants held positions related to their company's development. Their experience and current interest in development ensured high motivation and up-to-date knowledge about the topics discussed. Semi-structured interviews were conducted in which the following questions were asked: 1) What types of products and services does the company produce? 2) Who are the company's customers? 3) What do customers buy? 4) What is the company's business model? 5) What kind of development does the company expect? 6) What factors contribute to the company's development? 7) What factors make development difficult for the company? and 8) How do you see the future of the construction industry in Finland? The interviews lasted up to two hours and were recorded and transcribed. The main characteristics of the case companies are presented in Table 1.

Table 1. Company characteristics

Case	Sector*	Size**	Turnover M €	Role of interviewee
1	HPAC contractor	Small	5	CEO
2	Building construction	Large	550	Head of regional business unit
3	Construction products	Medium	12	CEO
4	Building construction	Medium	82	CEO
5	Building construction	Large	730	Head of regional business unit

* Classified by CFCI.

** Company sizes by number of persons employed, classified according to the EU Commission definition (2005) of small and medium-sized enterprises (Micro, 1–9; Small, 10–49; Medium, 50–249; and Large, > 250).

3. Results

The patent propensity rate is a potentially valuable indicator for innovative activities (Arundel and Kabla, 1998). Patents are the granted exclusive rights by a government authority for an invention, which must be a new method of doing something or a solution to a technological problem. The invention can be a product or a process.

3.1 Finnish construction patents

Patent data was requested on March 26, 2015 from the PRH, and the patent data that was acquired contained information on 7,330 construction patent applications from 2004 to 2014. Information extracted from the patent data file included the following: 1) application number, 2) year of application submission, 3) patent number, 4) year of issue, 5) year of publication, 6) patent applicant, 7) patent inventor, 8) International Patent Classifications (IPC) category and 9) abstract.

The trend line of the patent data in Figure 2 shows a peak in the number of applications (871) in 2010. The drop in the number of patent applications in recent years can be explained by an 18-month protection period starting from the time of submission; during the protection period, applications are not made public.

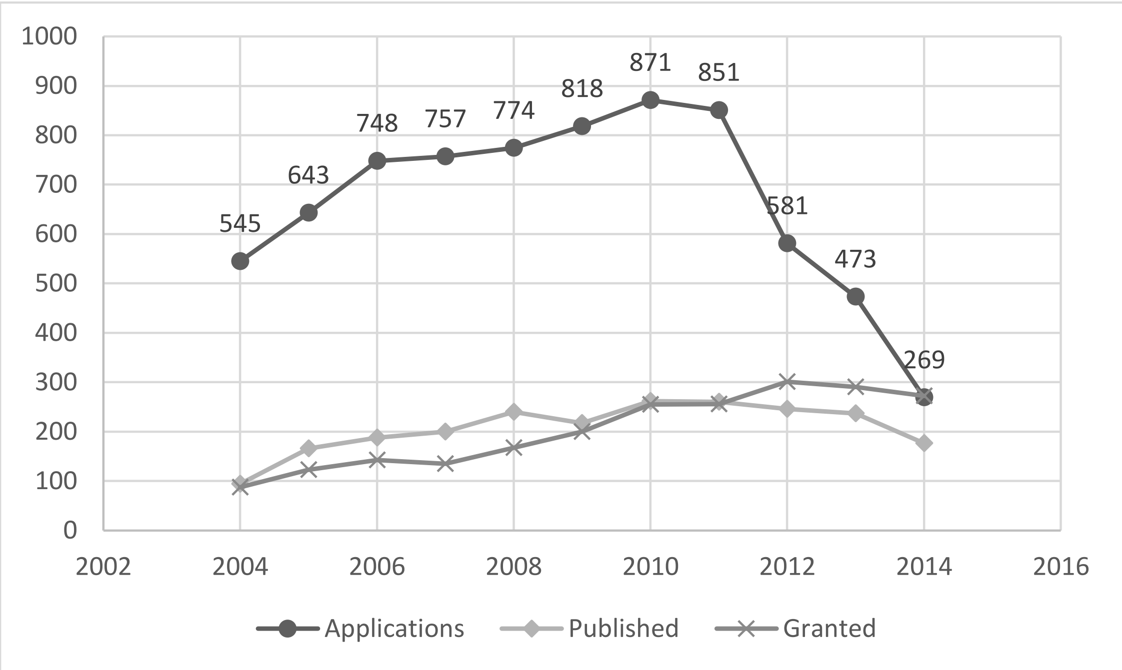

Figure 2. Patent applications and published and granted patents from 2004 to 2014

In addition, Figure 2 shows the trend of publication of Finnish construction patents from 2004 to 2014. The highest number of patents (262) was published in 2010. The lowest number of patents (94) was published in 2004. During the time interval from 2004 to 2014, the PRH issued the highest number of patents (301) in 2012 and the lowest number (87) in 2004. The trend of Finnish construction patents that are granted by the PRH can also be seen.

3.1.1 Role of patent creation by sector

In order to determine the patent creation per sector, the classes and subclasses of construction patents classified by the Finnish PRH (Appendix, Table 3) were reclassification to match the CFIC sectors (Appendix, Table 4). One CFIC sector, surface contractors, was not found in the PRH construction patent classification. The number of patents issued in the different construction sectors is illustrated in Figure 3.

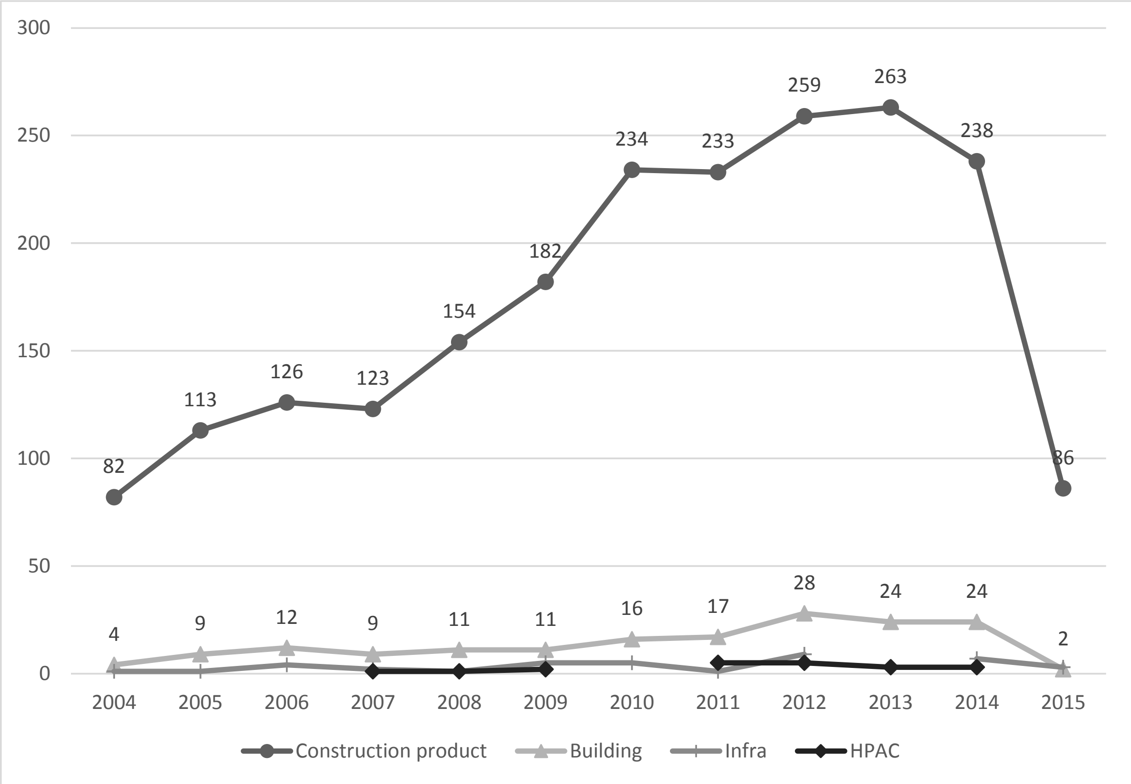

Figure 3. Patent creation per sector in the Finnish construction industry

The largest number of patents was issued in the construction product sector (90% of the total number), followed the building, infrastructure and HPAC sectors (about 7%, 2% and 1%, respectively).

3.2 Case interview results

Case 1: The company does not need to develop any of its own products because it is a subcontractor of HPAC installation services for municipalities and construction companies. The subcontracted installation services are the product that customers want to buy from it. The company does not have a written business model in use. It has pursued some development activities in the past, including implementing new marketing methods and changing the organisational structure. The main barriers for development are lack of available resources and time.

Case 2: The company offers real estate- and maintenance-based services and has several products: housing production, property development and commercial construction. The main customers are home buyers, apartment managers, institutions and the public sector. As a guarantee, the company solves customers' problems; in general, households, institutions and the public sector entities are looking for a service to help them find a place to construct a home or building. The company's business model is production, renovation and commercial construction of different types of housing. The company has made improvements in the areas of organisational structure and customer service. Some innovation has occurred in the construction of buildings. The main barriers to development identified in Case 2 are the attitude and ability of managers, outdated practices, budget limitations and overall mentality of the personnel. It is common for people to believe that investing in development is not guaranteed to get results.

Case 3: The company's products are concrete tiles, walls and pillars. The company also provides planning, delivery, installation and consulting services for business-to-consumer and business-to-business customers. Many customers buy concrete structures and installation services together. The business model is to provide concrete products. The company has made innovative developments in several areas, including products, processes, organisational structure and marketing. The case company has not been granted patents since they are issued by a head office. Factors hindering development activities are retirement of workers and personnel reductions.

Case 4: The company's main products are apartments and office buildings. Services are provided primarily for institutional real estate investors. Customers include companies, municipalities and institutions. These customers expect professional services and prefer to buy turnkey solutions. The company's business model is turnkey land development. The offer will provide solutions to the property developers. It attempts to do more than just offer the lowest price in the bidding process. The company has made organisational and process innovations. One example of development is an innovation in roof installation. Barriers to development are tight regulations, lack of resources and internal managerial thinking which will block progress.

Case 5: The company provides products related to customer demand and land development. The company offers real estate services for companies, municipalities, industry and institutional real estate investors. Customers buy a wide variety of products, from family houses and investment properties to office buildings. The business model is residential and commercial building and land development. The company has made several innovations in safety and organisation. A good example of development is a new system of schedule management. The projects themselves are the biggest barriers to development because customers tend to want the company to provide the same services they have always provided. The second biggest barrier is financial limitation.

Case 6: The company's products are housing, public buildings and renovation. The offered services are related to project development, and customers are municipalities, households and institutional real estate investors. Households hope to achieve their dreams by buying good-quality buildings. The business model includes land development and residential building. Development activities have focused on organisational, marketing and service innovations. Barriers to development are reluctance to assume risks and concern about investing in development activities.

The results of the case study are summarized in Table 2.

Table 2. Summary of development activities of case study companies

Case	Patents granted	Development types	Barriers
1	-	New marketing methods and reformed organisational structure	Lack of available resources and time
2	1	Organisational and customer service development	Attitude and ability of managers, outdated practices, budget limitations and overall mentality of the personnel
3	35	Product, process, organisational and marketing innovations	Retirement of staff and personnel reductions
4	-	Organisational and process innovations	Tight regulations, lack of resources and overall managerial thinking
5	2	Innovations in safety and organisational development	The projects themselves and monetary issues
6	1	Organisational, marketing and service innovations	Resistance of personnel and management's reluctance to invest in innovation

4. Discussion

As mentioned above and summarized in Figure 3, patents have a significant role in the construction product sector. The building sector also innovates, but innovations are related to organisation and marketing rather than to products or services. In contrast, the infrastructure and HPAC sectors do not generate a large number of patents.

As explained by Abbott et al. (2010), the measurement of innovation is quite difficult. From 2004 to 2014, 90% of the issued patents in the Finnish construction industry were in the construction product sector. The building sector was next, with about 7% of the total patents. The infrastructure and HPAC sectors had about 2% and 1% of the patents, respectively. This indicates that development activities occur mainly in the construction product sector, and invention very rarely takes place within the building and HPAC sectors. The surface contractor sector was not analysed in this study because this area was not included in the PRH construction patent classification index.

Many in the construction industry do not believe that investing in innovation will bring immediate profit, nor is it always certain that investment in innovation will bring benefit to the industry. Clients are considered the major drivers of innovation, so it would be beneficial to consider clients' thoughts when developing an innovation strategy. Similarly, other innovation drivers such as the business culture, human capital, organisational structure, technology, research and development, and partnering and knowledge management should receive equal focus from management.

The role of development activities in the Finnish construction industry is complex (see Table 2). Yet, development activities appear to be quite easy to implement in the construction product sector. This is easy to understand when one considers the goal of producing the 'right' products. The issue of development is more complicated in the other construction sectors. Even defining what 'product' companies offer to customers might be difficult. This is why 'service' types of development are more common in these sectors.

The interview results suggest that homes, offices and public buildings are common products of the Finnish building construction sector. However, some companies provide services instead of products. Households, municipalities, institutions, and institutional real estate investors are common customers of construction companies. It was noted that some companies did not have a clear business model. That is in line with the findings of Pekuri et al. (2013) that construction companies have significant problems describing their business models and value-creation logic. This leads to the question of what impact this has on the industry.

Globally, Finland ranks seventh in innovativeness after Sweden, Denmark, Switzerland, South Korea, the United States and Japan. South Korea's position as an innovative country has so significantly improved during the past few years that the EU now estimates it to be the world's leader in innovation (European Innovation Scoreboards, 2015). This would suggest that the Finnish construction industry should set the construction industry of South Korea as a benchmark and as a model from which it learn and improve.

Major barriers to development in the building construction sector, noted in the interviews, were the lack of resources and resistant attitudes at the managerial level. The need for workers with new and advanced skills at all organisational levels was expressed. Other barriers mentioned were monetary issues, such as limited budgets, old-fashioned thinking, strict domestic regulations and worker retirement. In addition, some of the interviewees said that the construction projects themselves block development in the building construction. The reason for this is that the project execution does not provide any room for innovative development. On the other hand, enthusiastic managers, new competitors, customers, goals for development projects, and quality of products and services were stated as factors that contribute to development.

The results indicate that development is occurring in the Finnish construction industry. Most of the interviewees appeared to understand that innovative ideas and activities are important for their companies to be competitive in the marketplace and that they must do more than just offer the lowest price in the bidding process. Many realise that innovations are essential to securing a solid position in the industry, whether these innovations are made by the company itself or in cooperation with universities or polytechnics. However, the interviewees did not believe that patents were the proper way to protect their innovations, which shows that the patenting process is not very familiar within the building construction sector. Also, the fact that many development projects are managed at the head office level might cause resourcing conflicts in regional business units.

The cause of this the lack of product and service innovation in the building industry must be seriously considered. One quite commonly cited justification is that the building industry is project-based and almost all construction work is carried out within a project context and project structure. A second one is that, since every project is unique, advantages from scale or repetition are not predictable. It must be examined as to whether or not these are sustainable justifications.

It is argued in this report that development activities are one of the major factors for companies to be competitive in the market. Gann (2000) mentions that competitive companies are able to make deep-rooted cultural changes while maintaining engineering and technical strengths. Thus, it is essential to focus on innovation activities.

5. Conclusions

The construction industry faces problems and challenges in many operational areas. In this study, the development activities of the Finnish construction industry were examined. Many earlier studies have claimed that construction is a very conservative field. The results of this study bear out this view. When looking at the construction product sector, development activities can be easily defined because it is a product-driven business sector. In contrast, other construction sectors do not seem to be involved in much development activity when the number of granted patents is used as an indicator.

The building construction sector implements development activities, but these tend to relate to the development of the organisation or internal processes. The reason is partly that ‘product’ as a concept is not as easily understood in other construction sectors as it is in the construction product sector. Moreover, large building construction enterprises face the challenge of head office centralization and managed development, and the ability to use resources for internal development varies among regional business units. In these cases, regional business unit managers will have a very significant role in education and in introducing new operational models.

The building construction sector is also disadvantaged by old-fashioned management models used by site and unit managers, a situation that may prevent introduction of new and advanced operational methods. Managers may ask why changes should be made if the model has operated well enough for the last twenty-five years. On the other hand, the significance of development activities has been rightly understood by some companies, and these companies have invested in development in response to market situations by changing their business models.

5.1 Limitations and future research

This study focused on the role of product and service innovations in the Finnish construction industry. The limitations of this study could be addressed by further research.

First, the number of companies interviewed in this study was limited. Second, further research should measure innovation throughout the patent life cycle. For example, a sample of granted patents could be selected, and a questionnaire related to the intended future use of the patented innovation could be sent to the company or creator. Survey results would indicate whether that particular patent was a successful innovation or not. This would give a view of the overall level of innovativeness within the construction industry. Additionally, the innovativeness of each construction sector could be evaluated and compared.

Finally, a deeper analysis must be done on how a project’s context and the structure of its working methods actually block customer preference-based innovations. Also, future research could benefit from a comparison to other industries, such as the shipbuilding and aerospace industries.

Innovative design and construction

Design Revolution for Affordable Housing in Tropical Country

Abd. Hamid Zuhairi[1], Gan Hock Beng[2] and Foo Chee Hung[1]

[1]Construction Research Institute of Malaysia, Malaysia
[2]G&A Architect, Malaysia
Email: zuhairi@cidb.gov.my

Abstract

Malaysian demographics are changing rapidly. With the increasing working population in major cities and towns, housing affordability problems among middle income households become widespread as many of these households are not covered by existing housing assistance programs. Prefabrication and modular construction are believed to be the solution for constructing houses that meet the vast number of demands in urban areas in a short period of time. Yet, as a housing strategy, it is still considered unresponsive to local climates and conditions with low acceptance rate, due to the lack of variability and an individual identified design. At this juncture, how prefabricated housing design can be evolved from mass repetitive production level to mass customization level that account for flexibility and variability is the primary issue to be explored. A good design can contribute to affordability through reducing the construction costs and the life-cycle costs while maintaining liveability. This paper discusses an alternative design strategy which is deemed to bring improvement to the country's prefab housing industry with respect to time, cost, and quality. The proposed design strategy entails open plan that enable retrofit and reconfiguration to be made quickly, economically, and repeatedly, without involving excessive site labour, time, and cost; as compared to the currently adopted design strategy which is associated with rigid structure, interlocking plan, and predetermined function. Besides, it is a combined design and construction system that makes use of the Industrialised Building System (IBS) construction method to produce a variety of housing design options that meet possible user requirements not yet identified at the design stage, while retaining principal uniformity to facilitate the execution of simple but accurate construction with a minimal initial cost. By taking into consideration the passive design strategies extracted from the tropical vernacular architecture – the traditional Malay house – the proposed affordable housing design makes possible the creation of dwellings that adheres to the context of contemporary technology, tropical adaptation, and cultural responses.

Keywords: Prefabrication, affordable, housing, design, customization, tropical country

1. Introduction

Due to increases in population, many world regions were forecasted to encounter an urgent need for new housing in the coming decades. According to a recent United Nations (UN) report, an additional three billion people will be needing housing across the world by the year 2030, which means that approximately 100,000 houses per day are required to be produced in order to meet such a pressing demand by 2020. Malaysia is of no exception in facing the mass housing problems when moving towards a higher level of urbanisation. In 2013, the Malaysian government, through the collaboration between the state governments and the private sector, targeted to deliver 1 million mass houses to the public in 5-year time, which is equivalent to an average of 200,000 houses annually. This challenge inevitably calls for the innovative building technology that has the dual benefits of economy as well as speed in construction.

Prefabrication is, no doubt, an obvious choice for the quick, efficient, and inexpensive housing construction and delivery, in meeting the ever-increasing demand for mass housing in the country. The strength of the prefabricated house lies in its lower capital and developmental costs by using purposely made components which are mass produced in great quantity. In some mass housing developments, industrial approaches to construction coupled with value engineering, were found to help slash cost by about 30% and delivery times by up to 50% (MGI, 2014). Since the primary determinant of mass housing construction is cost, prefabrication is always an attractive option to be adopted. However, there are some hindrances to change in this respect. Advances in technology may allow concept like standardisation and prefabrication potentially to address many of the problems facing the house-building industry, but questions arise whether mass houses being developed now are capable of adapting to occupant's ever-changing requirements, as the current demand for new housing seems moving towards mass customisation and agile production, which greatly increases the choices offered to customers rather than culminating in the standardised housing types of past experiences. Changes in the demographic make-up due to the diversity of family typologies and household arrangements have generated a need for housing that can adapt to different privacy, space, use requirements, and life styles. Prefabricated houses, on the other hand, have rigid structure, interlocking plan, and predetermined function, in which very few of them are open plan that enable retrofit and reconfiguration to be made quickly, economically, and repeatedly (Gan et al., 2015). This, consequently, leads to the question whether mass population is being accommodated in suitable dwellings. Similarly, given the need for sustainability and the generally important consideration of environmental and social values in the longer term, it is essential that a long term view be taken and that the needs for flexibility, maintenance and eventual disposal (or re-use) be addressed at the design stage.

Studies show that residents of mass housing in Malaysia are generally not satisfied with their housing conditions (Karim 2012; Isnin et al 2012), where a presumed need for flexibility in design, room size and fittings has precluded use. For example, criticisms have been made with regard to the People's Housing Project Scheme (PHP) (Figure 1) – an initiative by the government to solve the problem of existence slums and squatter areas – on the architectural design including the lack of storage area, small size and deep location of the kitchen, minimum external wall area, complicated partitions, less cross ventilation etc. (Sahabuddin and Gonzalez-Longo, 2015). Most of them end up renovating houses to tailor-suit their needs before occupancy (Rostam et al 2012; Nurdalila 2012; Erdayu et al 2010). This is largely due to the nature of the current mass housing architectural strategy, namely the convergent design system, which is a "one fits all" design initiative where housing is likely to be designed around the capability of a given product, instead of around the end-user (Zuhairi et al., 2015). Thus, houses designed for the average family are deficient in meeting the mass housing sustainability objectives as they are leading to further compromise the occupant's needs. Besides, the convergent design system implies extreme compartmentalization and dissociation of internal elements, where service spaces such as kitchen, bathroom, etc. are built internally by interlocking with space, making the service spaces difficult to interchange (Zuhairi et al., 2015). Houses designed and built with such system are solely based on the economic concepts of housing that only measure affordability, ignoring the potential of sustainable housing design that offers social and environmental benefits, not to mention in addressing the needs of the householder with regard to emotional satisfaction and economic performance.

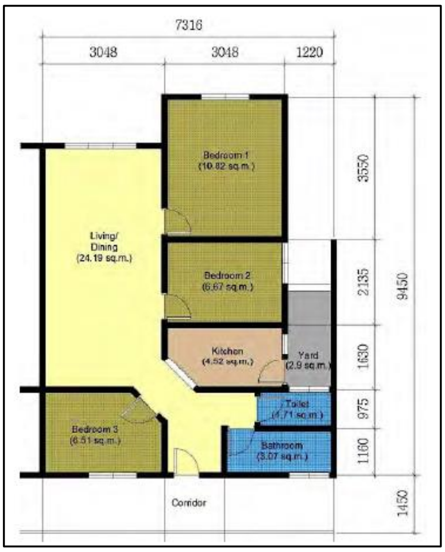

Figure 1: Layout plan of a PHP unit (Goh & Ahmad, 2011)

Apart from that, the potential social resistance to the ideas of prefabrication and standardisation in housing is still prevalent. Various perceptions, opinions, and images spring to mind when considering the prefabricated housing due to a number of buildings constructed in the past were judged to be of poor quality. In fact, prefabricated housing in Malaysia has been plagued with bad publicity such as leakage, inflexible for the repair and maintenance, as well as a resemblance of low cost housing projects which are basic and pay minimal attention to the aesthetics of the building (Figure 2). While some of the problems to prefabricated housing may not be an issue now with the application of new technology, such as using advanced water-proofing or innovative jointing method for solving the leakage problem, the image of prefabricated housing is still strongly tarnished by the general perception that the lifespan of such housing is likely to be less than that of "conventional" built housing – consists of a reinforced concrete frame and brick, beam, column, wall, and roof, which was cast in situ using timber framework. It is the programmes of poor quality and poorly designed prefabricated housing that have given rise to a notion that the process of prefabrication per se, rather than particular products, was at fault. On top of that, prefabrication construction in Malaysia has been associated with a cost increase of 10% compared to conventional construction (CIDB, 2007). Since moving towards mechanized and industrialized systems involves high capital investment on heavy equipment and mechanized construction facility, along with availability of cheap foreign labour in the country, the industry players are unlikely to switch to an unfamiliar system in order to secure their projects, particularly for those small contractors who involved in the small scale development (Foo et al, 2015).

Figure 2: Examples of low cost housing projects – Tunku Abdul Rahman Flat in Kuala Lumpur (left) and The Rifle Range Road Flat in Penang (right)

2. Good Design for Mass Housing

Regardless of the barriers that influence its uptake among the industry players, prefabrication construction is still believed to be the appropriate solution for today’s mass housing problem. To allow for the successful application of prefabrication, in Malaysia particularly, the following past mistakes need to be recognised and addressed: (i) Quality – previous lack of quality has led to the perceived reduction of value associated with prefabricated housing; (ii) Attention to detail – poor detailing in the past has led to technical problems and a general perception of poor value; (iii) Life cycle performance – failure to consider the practicalities and costs associated with maintaining these buildings had led to some prefabricated housing becoming difficult to maintain. Hence, how prefabricated housing can evolve from the mass repetitive production level to the mass customization level that account for flexibility and variability, as well as becoming responsive to the local condition and social acceptability, is worth to be explored.

According to Evans (2014), a good design can be the critical difference between an affordable development that succeeds – one that satisfies its residents and neighbours, enhances the community where it is built, and continues as a stable part of the community for decades – and one that does not. Given that each dwelling unit is a primary structure which would contribute to the quality of life, and the root causes leading to housing quality problem are identified as issues related to housing layout and design, surrounding environment, maintenance, location, amenities, and building material (Živković and Jovanović, 2012), house builders should be aware of the potential for a good design in responding to the evolving social behaviour, and strike to take advantage of technology in the housing production process through integrating housing design with industrial construction system. In other words, each dwelling unit should be designed, in such a way that it is economically and easily adjustable, while adheres to the context of contemporary technology, tropical adaptation, and cultural responses (Gan et al., 2014). The key element for a good design is the realization that lifestyle – as one of the defining characteristics of peoples' lives as citizens, consumers, and householders – is a feature that shifts in accordance with a dynamic lifecycle process. A home that can be altered with minimum effort and expense at a time of change in the lives of its owners is a home that evolves with the lifecycles of its household rather than becoming rigidly obsolete in the conventional manner (Friedman and Krawitz, 1998).

The present paper, thus, proposes a flexible housing design system for the modern urban mass housing in tropical country. By adopting flexibility as the inherent architectural design strategy, the system is able to provide the physical spatial arrangements that are conductive for the socio-cultural wellbeing of a community along while complementing the environment. Besides, the system combines both machine production and mass customization, offering more than 10,000 possible designs including prefabricated structures, factory-made structures, dwelling plan and flexible design, to provide an affordable and sustainable housing for all. It makes possible the creation of dwellings which may grow old yet without becoming obsolete; incorporating the latest design ideas and technologies, yet have a sense of history on the Malaysian housing design (the *rumah kampung* design); allowing the communities to live for generations, yet incorporating the potential of adaptation.

3. Divergent Dwelling Design (D3)

Divergent Dwelling Design, or D3 in short, is a combined design and construction system directly responses to the fundamental demographic and economic pressure that heightened the need for an appropriate solution for the urban mass housing. It makes use of the open plan design concept and the Industrialised Building System (IBS) construction method, to produce a variety of housing design options that meet possible user requirements not yet identified at the design stage, while retaining principal uniformity to facilitate the execution of simple but accurate construction with a minimal initial cost.

The proposed D3 basic architectural plan is a square shaped plot (Figure 3), having a plurality of "dynamic" space lots (where the bathroom, kitchen, and other dwelling services located) arranged peripheral of the plot so as to be in contact with the outdoor environment; and a plurality of structures such as the dining room, bedroom, or any other spaces located in the "core" space lot which is capable of being arranged, modified, and customised in plurality of designs according to the user's needs. While the plot is standardized to allow for efficient manufacturing, it can take any desired shape including square, rectangle, as well as other polygonal shapes (Figure 4). With the built-in architectural flexibility, D3 basic dwelling unit can be divided into more than one plan, in which the occupant can choose the floor plan they want to live before moving in, thereby achieving harmony between the basic structure and the various sizes of dwellings in the long term. This is similar to the automotive industry, where each individual functional unit is freely bonded with the core structure to serve different occupants' requirement.

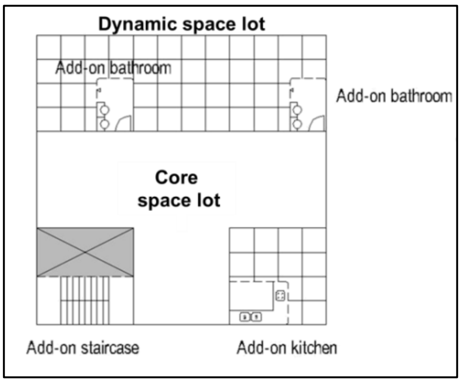

Figure 3: D3 basic architectural plan

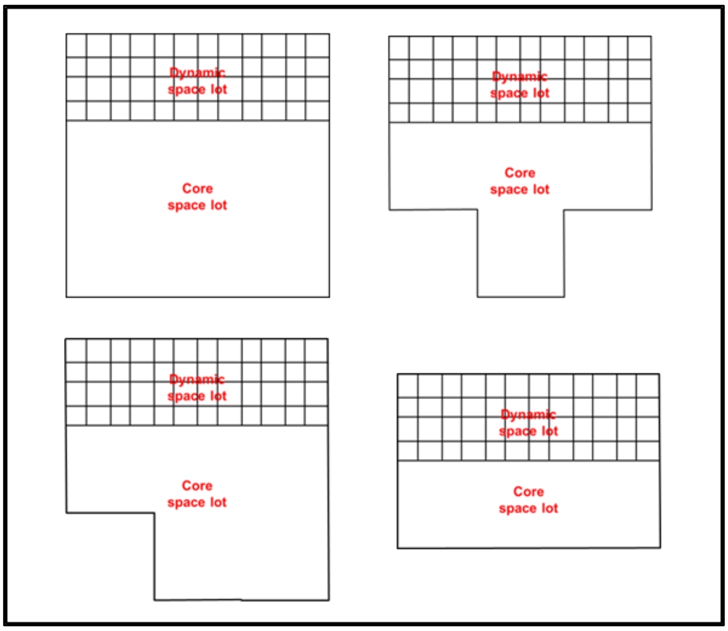

Figure 4: Various shapes of D3 basic dwelling unit

Every D3 building is designed and built in such a way that both the structure and infill of the building are treated as separate entities in order to optimize the efficiency of building assembly and modification. As depicted in Figure 5, the basic layout can be configured into various plans, simply by partitioning the core space lot or rearranging the location of bathroom and kitchen within the dynamic space lot. In other words, there is no one fixed plan in D3 design system but a flexible plan that houses endless of possibilities. Owning to the use of a number of interchangeable component sub-assemblies, D3 makes possible the transfer of construction process from building to manufacturing, with component manufacturers and end-users playing a much larger role in the design process. For example, the bathroom, kitchen, partition, façade etc. are mass produced which then divergently attached to the building structure (Figure 6). The occupant has wide spectrum of choice with regards to products in the market. Since each system is independently manufactured in a controlled environment, the development entails the use of technology and innovation, without the involvement of excessive site labour, time, and cost. In this sense, D3 comprehends the advances of science and technology over time, leading to a faster production at economical rate.

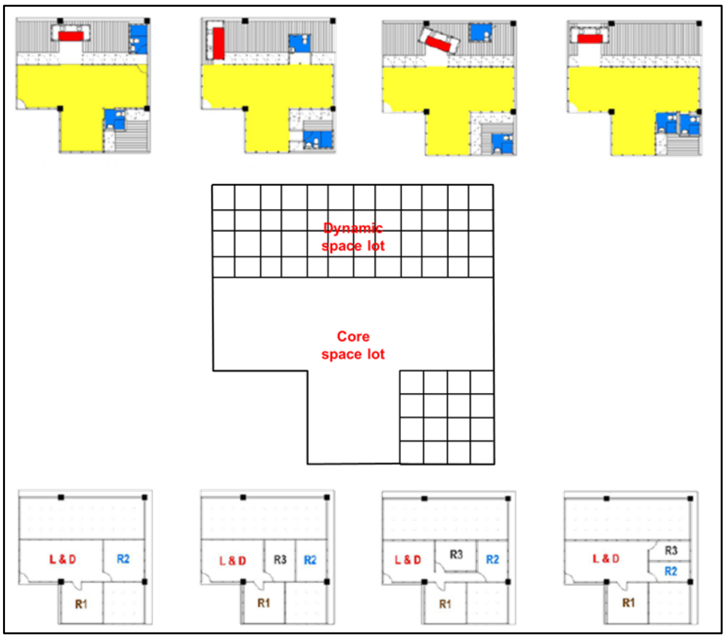

Figure 5: Different variations in the arrangement and partitioning of D3 basic dwelling unit

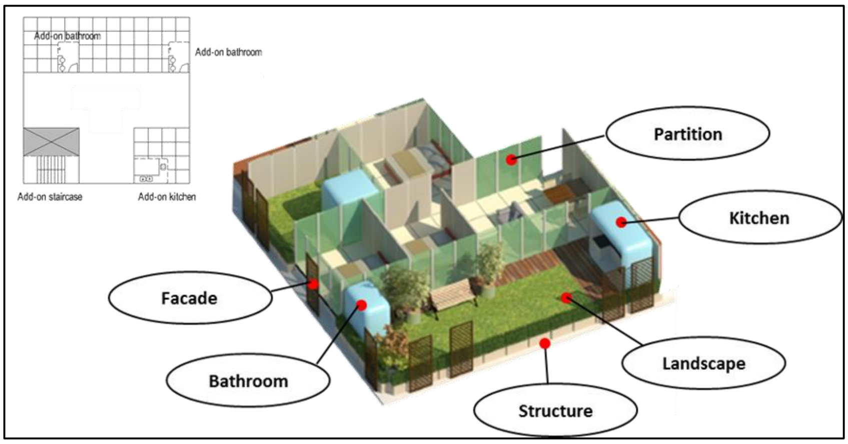

Figure 6: D3 independent building systems

Once the design system is in tandem with serial production and standardization, there will be no bounds for the development of a sustainable community that can accommodate a wide diversity of users and household types. Prospective occupants can choose from a catalogue of available components which are tailored to individual lifestyles and budgets. This enables the occupants to consume only the type and quantity of features they currently require or can afford. For example, a variety of kitchen options that suit a wide range of household lifestyles can be offered by the manufacturers without significant increase of their administrative and operational costs due to the prefabricated nature of kitchen cabinetry. Besides, the variety of configurations available caters to desires for increased work surfaces, space economy, and the inclusion of washer, dryer and recycling facilities within the kitchen. Similarly, the bathroom requirements also vary according to the occupants and their individual scenarios. Normally, two bathrooms will be provided for every affordable house in Malaysia. However, the number of bathroom is not restricted in D3 housing; if the number of occupants and their schedules justify for another bathroom, D3 open plan concept would satisfy this requirement by balancing the size and location of this additional bathroom with the remaining spaces in the dwelling unit. Consequently, the bathroom options offered by D3 housing can range in size from powder rooms to complete bathrooms with shower, bath, toilet, and sink (Figure 7). Since every individual dwelling unit is flexible enough to adapt to the changing needs of both existing families and future users, the combination of these units will enable a variety of sustainable habitual spaces to be processed, which then can constantly renew themselves without becoming obsolete (Figure 8).

Figure 7: Examples of available modular bathroom in the market

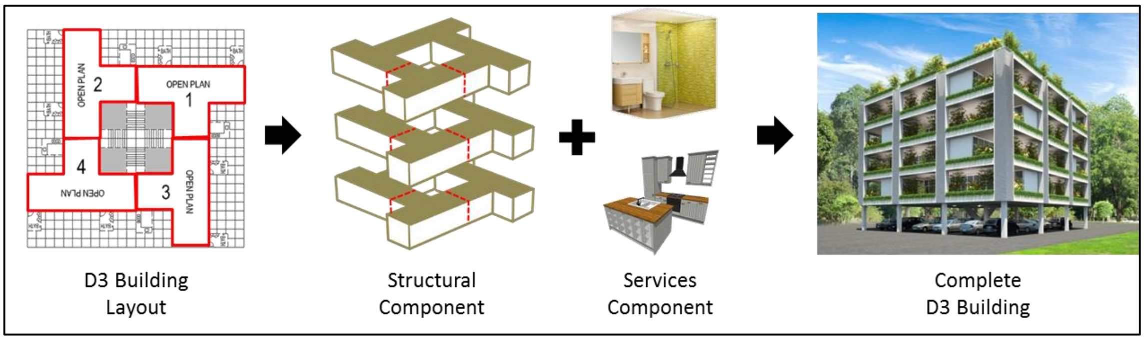

Figure 8: Formation of D3 building through combination of individual flexible dwellings

The principles underlying the design of facades are analogous to those governing the structure and plan: flexibility and individual identity. By positioning the dynamic space lot in the peripheral of the plot, a setback of walls is created where no external walls to be in contact with the outdoor environment. Such setting can be well-adopted in the apartment development, imparting a sense of individual identity and differentiating vertical occupancies or uses, yet avoiding the extremes of monotony and theme park atmospheric elements (Figure 9). One of the most common drawbacks of prefabricated housing is the homogenous and repetitive nature of the development, which is a by-product of the economies of scale. The value of providing a diversity of appearances is that it satisfies the individual user's personal requirement for identity and self-expression, counteracting any potential feeling of anonymity resulting from increased density, and it incorporates – or rather predicts and pre-structures – the inevitable variety caused by change overtime. Residents are able to explore various options in terms of appearance, style, fenestration, and materials used through the participation in conjunction with the builder.

Figure 9: Examples of flexible façade combination

4. Functionality and Liveability through D3 Efficiency

As stated by Barlow (1999), current housing construction situates the industry somewhere between craft forms of production and mass production, which tends to display relatively low quality consistency, measured by the amount of rework required on completion (Figure 10). This strongly contrasts with the car industry which has been pioneering lean production concepts for many years and may be moving towards agile production as customer input into the final product, quality and after-care grow. As a housing design system that seeks to avoid the rigidities of prefabrication and less effectiveness of conventional construction, D3 has the potential to help boost a greater productivity, better quality, and an assurance of a growing and interested housing market. With the delivery of highly customized products at costs comparable with mass production, it is possible to make prevalent the concept of mass customization in the Malaysian construction industry. The following sections are devoted to describe how the housing functionality and liveability is achieved with D3 design system, in terms of construction, space, and energy.

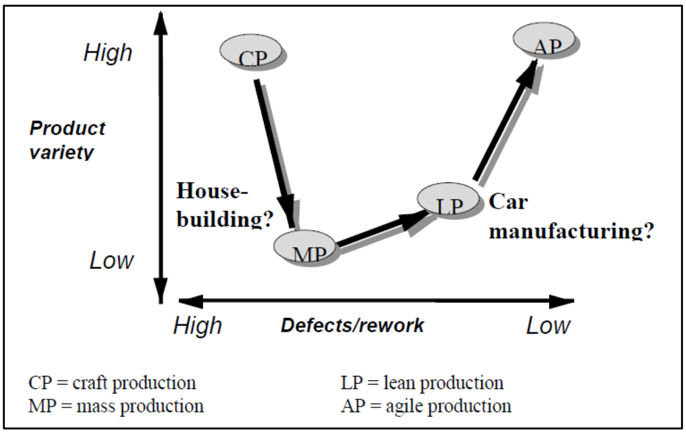

Figure 10: From craft to agile production in the housing and car industries (Baker, 1996)

4.1 Construction Efficiency

Construction efficiency is among the most effective strategies for decreasing the cost of housing construction without reducing its liveability (Feldman and Chowdhury, 2002). In the case of D3 construction, a modular system prevails in an attempt to minimize building costs, as well as to execute simple but accurate construction. The 7.2m x 7.2m module allows for a strong element of flexibility with regard to a variety of building configurations (Figure 11). This unit module with its multiples and subdivisions form the basis of all dimensions of the dwellings. The advantage of the employment of this single unit module is that all locations and sizes of the parts with respect to the whole are precisely identified during the construction process (Figure 12), and thus, no obscure or arbitrarily unrelated measurements are involved in the unit system. This also leads to other advantage, such as the standardization of many building components (prefabricated beam, column, and slab) for mass production in manufacturing. There is usually a cost with the provision of a structure that allows for flexibility and adaptability. In a departure from the conventional mass housing design, however, D3 design system allows planners and builders to incorporate various housing types within a single unit module in order to respond to a diverse range of values, incomes, and households (Figure 13). With such ability, a wide range of housing size is covered under one design plan, be it a 450ft^2 studio type dwelling, 700ft^2 low-cost housing, or 1,000ft^2 affordable housing.

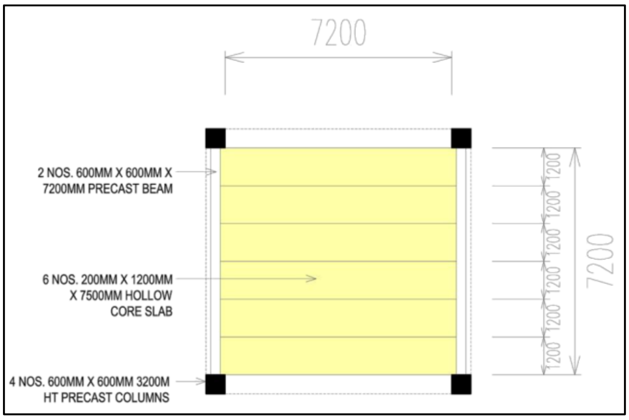

Figure 11: A D3 typical structural unit

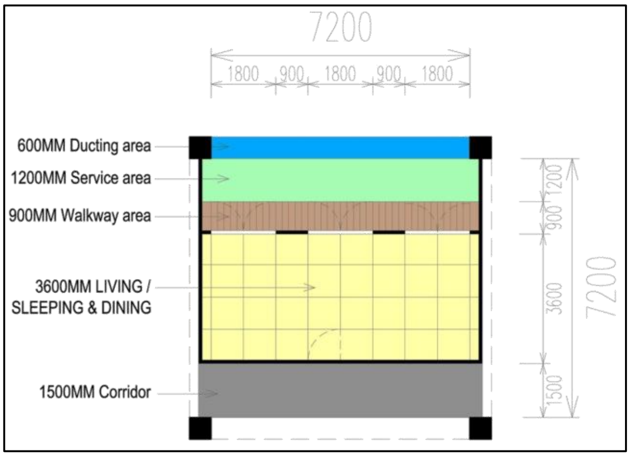

Figure 12: A D3 typical functional unit

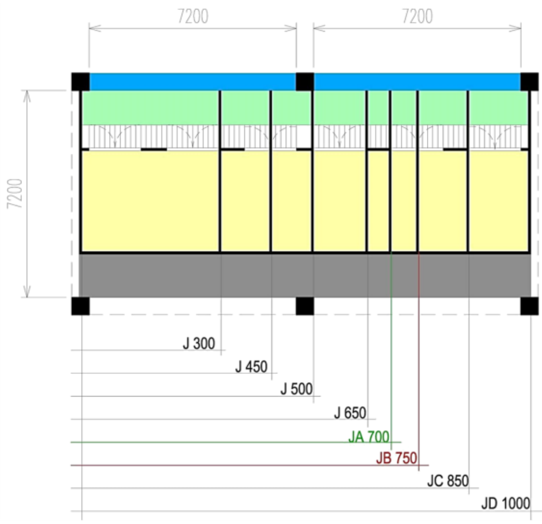

Figure 13: Different types and sizes of D3 housing with a single modular unit

All prefabrication of structural components is made in an off-site factory and is regulated with regard to the single unit module, namely column, beam, and hollow core slab. When all components are delivered on site, they are assembled to become a home (Figure 14). Assemblage of components is easy and simple, where altering or replacing components is much the same. The construction system is a kit-of-parts solution to the affordable housing problem that does not require a highly skilled work force or special machinery. By incorporating IBS into the construction process, a compressed construction schedule is not only cost-saving in and of itself, getting the building into productive use sooner and reducing finance periods, but, especially in times of significant inflation, compressed construction schedules save additional significant sums. Therefore, a building that adopting D3 design system can be constructed at a faster pace and arranged in multiple manners, to achieve high density in the most comfortable spatial design environment (Figure 15).

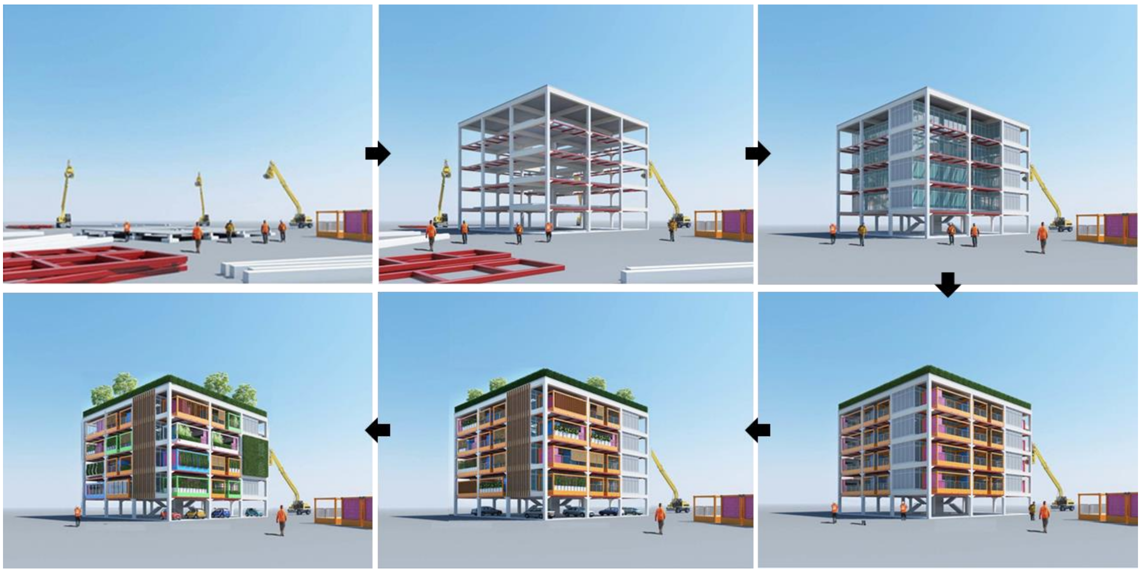

Figure 14: Comparison of trades and time frame between conventional and D3 construction

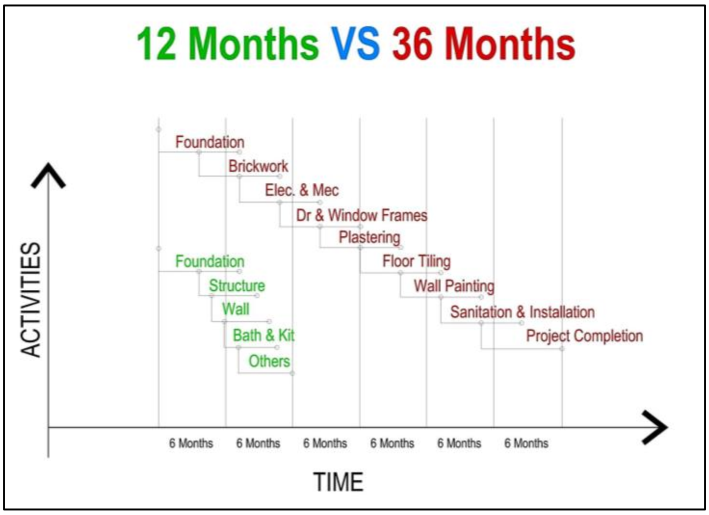

Figure 15: Comparison of trades and time frame between conventional and D3 construction

Besides, the use of 100% machine produced components allows both the cost and structural integrity to be effectively reduced because using modern construction materials, such as lightweight partitions, modular bathroom and kitchen can all save time. In traditional construction, each sequence of construction involves different work crews that lead to the conflict in scheduling. Some trades such as formwork or pouring concrete may even stops or dramatically slow the work of others. The on-site construction of a bathroom, for example, requires nine major steps and the inclusion of more than thirty parts/components (Figure 16); as compared to a modular bathroom which is manufactured in the factory environment and is delivered to site as a complete unit. In addition, the conventional practice for installing the plumbing system involves the cutting and assembly of the various pipelines and fittings. It is obvious that prefabrication of such plumbing installations in a factory is potentially a more efficient and economical procedure, particularly when a number of essentially identical plumbing installations are to be made, as in the case of multiple dwelling, units, hotels, apartment houses, schools, and the like. This is the key of reducing conflict in scheduling, where trades and building parts are greatly reduced by coordinating dimensions and positions instead of improving on site by cutting to size. On top of that, the whole project can also benefit from those intangible benefits, such as site cleanliness, less labour, less material wastage, shorter construction period etc.

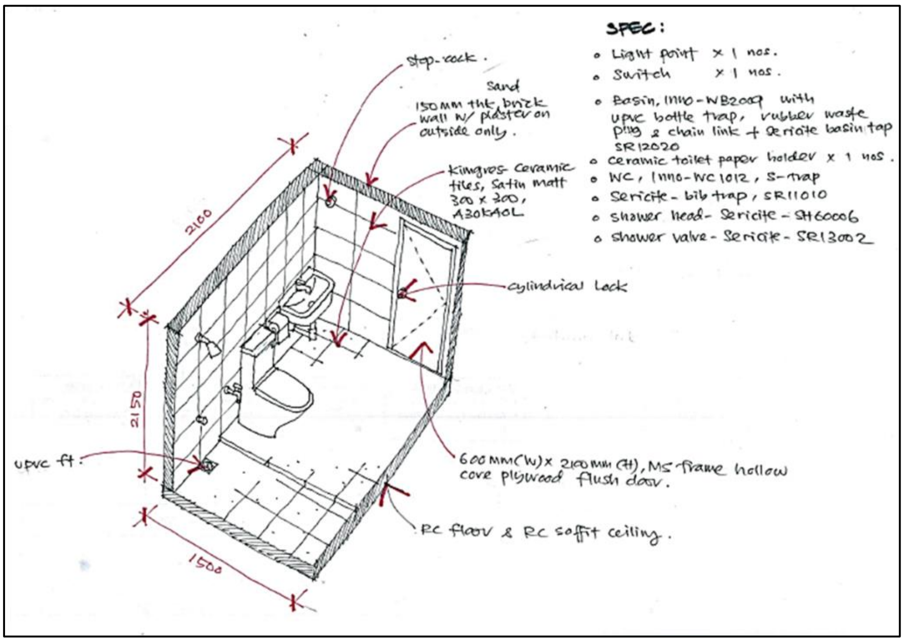

Figure 16: Parts and components of building a conventional bathroom

4.2 Space Efficiency

Structural system, as rigid and unchanging part of the housing unit, dictates the degree of flexibility of spatial unit set (Živković and Jovanović, 2012). The key role of this part of design process for housing unit flexibility is conceivable through the fact that these parts are the most inflexible elements of the unit. The position of technical installations is another basic unchangeable aspect of residential space. The issue of structuring the technical core is, thus, important to be considered and resolved in the initial design phase, so as to give more flexible solution in exploitation. In D3 housing design system, space efficiency is achieved without compromising the dwelling liveability by several approaches. First, all structural elements are located at the exterior of the layout to allow for unlimited unobstructed clear spaces that can be freely arranged over the life of the dwelling unit. The dining room and bedroom are distributed along the core space lot, which is capable of being arranged and modified according to the user's needs (Figure 17). The main entrance to the house is adjacent to the living room. All the living room and bedrooms are made to be accessible to the "landscape area", which also functions as the laundry area or open porch, providing an excellent means of open-air drying.

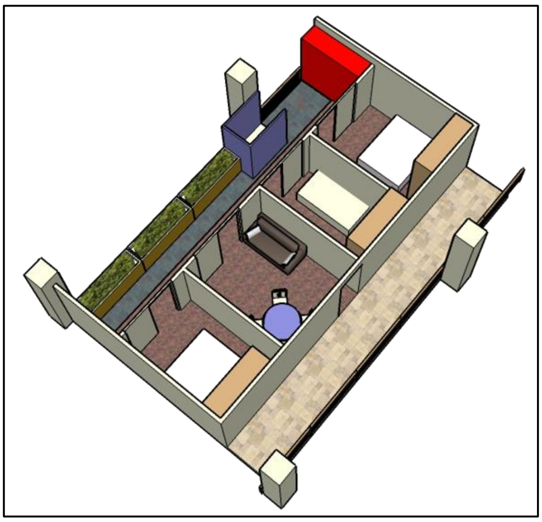

Figure 17: A typical 750ft^2 D3 dwelling unit

The kitchen and bathroom are grouped in the dynamic space lot in order to concentrate the plumbing system, so that economic maintenance and cleaning are possible. This concentrated plumbing system consists of a modular system for routing building utilities. The current practice in many multi-floor buildings is that the distribution ducts for electrical conductor and plumbing are installed inside the concrete walls and floors. The limitation of this setting is that the arrangement of the distribution ducts cannot be changed once it is installed. Also, there are a number of times where moisture is found on the floor due to the condensation and leakages of the ducting system. To overcome the inflexible nature of the technical installations, a modular system for routing the building services connections is introduced, which is an integrated service panel installed along the periphery of the building structure carrying the building services connections including but not limited to the electrical connections, plumbing connections, solid waste transfer connections, gas supply connections, heating, ventilation and air conditioning connections, fire sprinkler piping connections, and other communication services connections associated with a building structure (Figure 18).

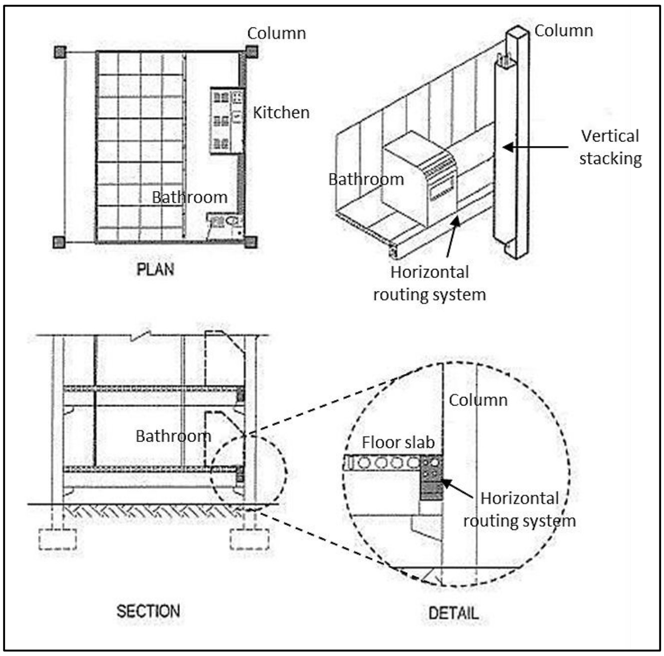

Figure 18: Configuration of building structure installed with the prefabricated integrated service panels

This routing system is easily installed and can be reconfigured whenever desired. It consists of an elongated rigid casing, having a top portion, a bottom portion, a plurality of side surfaces and a pair of ends that are configured for connecting with other rigid casings and other external building services connections (Figure 19). The top portion of the rigid casing is open to connect with the building services connections and for allowing access to the elongated compartments inside the rigid casing. An adjustable top closure means is used for closing the top portion of the rigid casing. The side surfaces of the rigid casing are provided with a number of external connectivity means configured for connecting with the building services connections. The routing system can be installed in a combination of arrangements, either at the subfloor position of the building structure, or to be vertically attached to the walls of the building structure, or even to be attached to the roof of the building structure. The interconnection means of the prefabricated integrated service panels is compatible with existing piping connections and can be installed with existing plumbing and electrical connections and existing interconnecting means for the plumbing and electrical connecting systems.

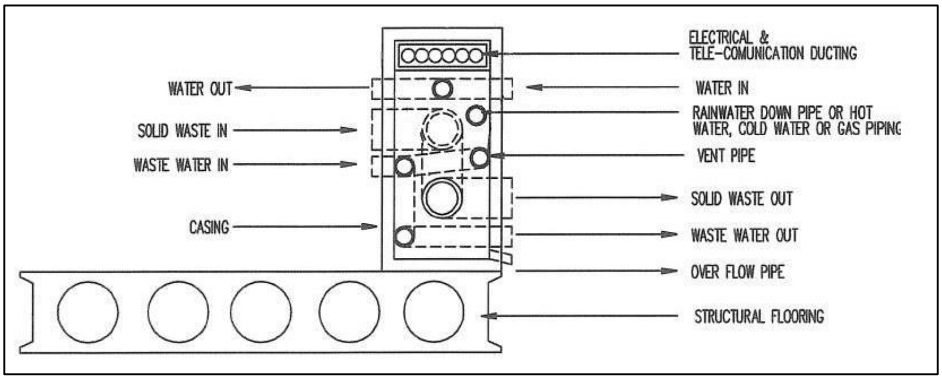

Figure 19: Side view of the integrated panel for routing building utilities

Flexibility in D3 design system is further achieved by using movable partitions. Since common walls within a dwelling unit are non-load-bearing walls, the dwelling unit floor areas can be arranged independent from boundaries to suite the size of any uses. The sustainability initiative here focuses on providing spaces to be used for a variety of purposes over time, be it the changes of household demography or the changes of resident's living satisfaction. Since this kind of functional change can be done by merely switching of the independent units within the configuration through a simple process, the function of the dwelling unit can be cultivated and adapted to the occupant's need whenever it is required. By enabling the floor plan to be adapted to the future users and the changing needs of families, D3 unit plan is able to take into account different family types: (i) dynamic family which is likely to have more children in future, and is thus requires a high degree of space flexibility to cater for continuously changing and increasing needs; (ii) stable family which is not going to have any more children (either the children have left home or are too small to leave home) and thus requires a relatively lower degree of space flexibility; (iii) stagnant family which is expected to live in the same dwelling for a long time and thus has sufficient opportunity to benefit from flexible building elements, which provides for lower life-cycle cost of such elements. Furthermore, a residential space can be converted into a café by just incorporating a larger kitchen and more toilets; a laboratory or playroom or computer room when added with a unit space for teaching can be used as an educational institution. So similarly the kind of unit space or constant space can change its function from residential to commercial, without ever needing to change the basic unit.

4.3 Energy Efficiency

Malaysia is situated in a maritime equatorial area, where the climate is generally the same throughout the year, with uniform temperatures, high humidity, light winds, and heavy rainfall (Hyde, 2008). The very nature of the Malaysian climate necessitates mechanically ventilated or air-conditional interiors, especially in urban areas. However, poor design and indiscriminate use of air conditioning have resulted in huge increases in energy use. Passive and low energy design strategies are too often excluded from the affordable housing projects because they are deemed to add cost to the construction, though they are the solutions for a sustainable future. In fact, it is possible to attain energy efficiencies without incurring additional costs. As pointed out by Feldman and Chowdhury (2002), energy efficient design contributes to environmental sustainability and saves life-cycle costs. D3 directly responds to the fundamental demographic and economic pressure that has heightened the need for a new housing alternative which appropriately integrates affordability and sustainability. To ensure mass housing populations could enjoy eco-housing with affordable price, affordability is designed in at the beginning by adopting a simple design layout, which is flexible enough for adaptation and yet suits to the tropical climatic condition.

The passive design strategies adopted in D3 design system is inspired by numerous features found in the traditional Malay house that area geared towards providing thermal comfort. With a direct dependence on nature for its resources and embodying a deep knowledge of ecological balances, the traditional Malay house is best reflecting the bioclimatic housing, using various ventilation and solar-control devices, and low-thermal-capacity building materials (Figure 20).

Apart from being well adapted to the environment, a very sophisticated addition system was also developed to allow the house to be extended in line with the growing needs of the user. Such an autonomous housing process, which is using self-help and mutual-help approaches, can throw some light on the development of a modern autonomous housing model. In general, the experiences gained from the traditional Malay house evidenced that an appropriate house in tropical country should provide for the following: (i) allow adequate ventilation for cooling and reduction of humidity; (ii) use building materials with low thermal capacity so that little heat is transmitted in to the house; (iii) control direct solar radiation; and (iv) control glare from the open sky and surrounding

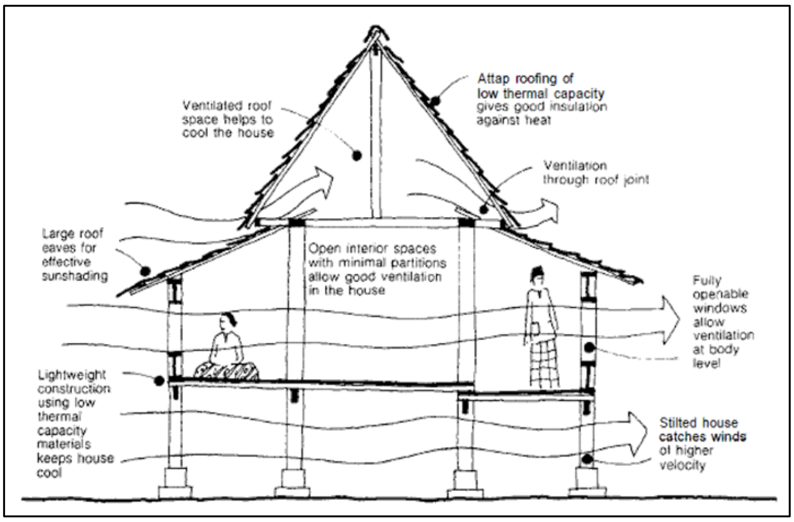

Figure 20: Climatic design of the traditional Malay house

In the case of D3 design system, cross ventilation is optimized by having an elongated dwelling shape together with minimal partitions or interior walls. This is not only allowing for easy passage of air and cross-ventilation, but also encouraging a good lighting of the interiors, as well as the flexible use of space (as described in Section 4.2 – Space Efficiency). Besides, the parallel arrangement of windows and the placement of high louvers on the internal walls of each bedroom also ensure adequate wind from outside flows through the house. By setting back the exterior walls 2.1m from the peripheral of the dwelling, no walls are exposed directly to the outdoor environment. Solar radiation is, thus, effectively controlled with the large thatched upper floor ceiling that acts as the overhang. Together with the installation of adjustable louvres or grilles as building façade, a barrier is created which not only provides good shading and protection against driving rain, but also to some extent maintain the quality of openness for ventilation and outdoor views. The setback also creates an open porch that makes possible the occupants to enjoy the open-air landscape. With careful planting or selection of vertical green, the open porch can function as a buffer corridor that aids in air circulation. The presence of air movement will then enhance the evaporative and convective cooling from the skin and can further increase the occupants' comfort. Glare, which is a major source of stress in the tropical climate, is effectively controlled by using louvres or grilles which break up large bright areas into tiny ones and yet allow the interiors to be lighted up; or by planting less reflective vegetation. Figure 21 illustrates the interior views of the D3 housing.

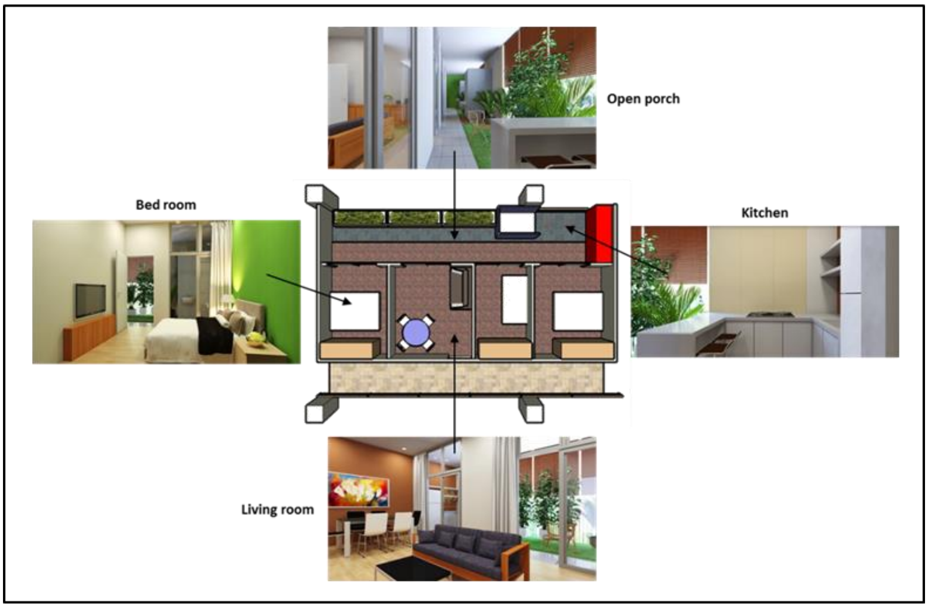

Figure 21: D3 plan and its interior views

The use of reinforced concrete skeleton structure ensures a lot of the qualities that aid flexibility in housing design, which then contribute to the housing affordability and sustainability. First, prefabrication construction allows for the design of flexible internal space layout are variable to accommodate different family structures. The constant improvement in prefabrication technology that supported by the incorporation of lightweight, durable, smooth edged, space efficient, and universally adopted specifications will ensure that mass housings remain affordable and sustainable for the long term. Second, the use of concrete as the main structural material contributes to a wide range of inherent benefits at no extra cost, such as its proven integral fire resistance, high levels of sound insulation, and robust finishes. Through its very nature, concrete provides robust surfaces for walls, partitions, columns, soffits and cladding that are easily sealed and free of ledges or joint details. All these may finally lead to the lower maintenance costs of the building while set in motion an efficient, cost effective and practical method for solving housing needs and overcrowding concerns in urban areas. However, realizing that the concrete industry is responsible for 10% of worldwide CO_2 emissions, the limited use of concrete is also to be considered in D3 design system. For example, complicated wall arrangements are avoided in D3 housing, so that less concrete wall panels are used as internal partition. Within a typical D3 dwelling unit, walls that facing the outdoor environment is eliminated with the installation of aluminium sliding doors. Since the infills of D3 housing are prefabricated materials that are subject to change, lightweight materials that have a low heat storage capacity such as gypsum board and plasterboard with insulation can always be used in replacement of the existing one. In short, flexibility in terms of architectural and construction process is the key strategy of sustainability in D3 housing.

5. Conclusion

Affordable housing in the past has never been designed to last. It was aimed to provide a short-term solution – maximum number of houses in the shortest possible time – to meet the urgent housing demand as if poverty and lack of affordable housing is a short-term problem. Although it is a government effort in providing adequate and affordable housing for the general population, the new contemporary household with its diversity of interior design needs in their consideration of future housing prototypes can no longer be ignored.

D3 design system introduced here can generate a better and cheaper habitat option through the application of existing science, technology and machine production capability. This concept is able to provide a new dimension in the design of comfortable and sustainable housing for the tropical country. The importance of this housing solution is reflected in its ability to solve the housing problems of especially the poor in a manner that is most appropriate to their socio-economic and cultural needs, by using environmental friendly method, contribute to the sustainable development of the construction industry, offers what people demand from a house and that they can live how they want to within it, by taking into account (i) the spatial and functional arrangement, (ii) the potential to expand spaces for increased occupant's usage, (iii) maximizing natural lighting and ventilation, (iv) the continuity of the traditional housing concepts into a modern contemporary residential development. On a much larger scale, D3 can facilitate the shift towards a higher quality housing in the country, and eventually create sustainable dwellings for everyone in anywhere in the country.

Comprehensive Planning as a Platform for Environmental and Economic Development of Urban and Rural Areas

Jyri Nieminen
Sweco Strucures Ltd, Finland
Jyri.nieminen@sweco.fi

Abstract

Urbanization in China is vast. It is foreseen that in the near future 75% of the population lives in the cities while the present share is less than 50%. The rapid urbanization has led to major problems concerning urban development and environment: Unsustainable planning, pollution and severe deterioration of ecosystems and poor quality of buildings, especially housing. Land use rights have been the engine of this development. However, revitalizing the economic model is the key to transformation of the Chinese cities. By adopting new approaches to urban policies can help to change the path China is on. Innovative urban planning and design is one of the key development areas for healthier cities and districts. At the same time it serves for both economic development and environment.

Co-operation between different stakeholders is mandatory in the development in sharing resources and possibilities. ChangJi area in Jilin province locates between two cities, Changchun and Jilin. Both cities have agreed to develop the area according to sustainable planning and design approaches. Re-thinking urban and rural structures, transport, agriculture, industrial development and industry structure and energy services aim at environmentally sound and livable urban areas and prosperous rural villages. The regional development in ChangJi focuses on piloting new methods for comprehensive and master planning and exploring possibilities on low carbon development. Environmental and economic development go hand in hand in the execution of strategies for opening up for international approaches, technological innovation, ecological city, intelligent city, urbanization system, social mode with planning as the platform. The first phase of this development was finalized in August 2015.

Keywords: Urban planning, environment, energy, emissions

1. Introduction

The urban and regional planning processes are tending to draw up optimal solutions. This will too often include solutions that are not correlating with the future reality and will further lead to very unsatisfying results; wrong investments in infrastructures or buildings, failing in function, identity and attraction among others. This can never be fully prevented but it can, however, be reduced by analyzing how the different solutions are dependent on certain circumstances.

Land use planning aims to promote economic community structure and sustainable land use. Goal is to ensure a safe, healthy, pleasant, socially functional living and working environment which provides for the needs of various population groups. China's urbanization is rapid. Roughly 300 million people will move to cities in about 25 years. In the urbanization process the land use planning has served more for the economic growth than for the basic aims of planning. The consequences include poorly planned residential areas, pollution due to increasing energy production and industrial activities, car transport and neglecting the environment sometimes totally.

The rapid urbanization has increased energy demand in China significantly. Energy use in public sector increased by 15% between 2006 and 2010. The increase in energy use in residential sector is estimated 150 – 300 % between 1996 and 2006 (Amecke H et. al., 2013). ChangJi area locates in the severe cold climate zone in North-East China, Figure 1. The annual energy consumption in present residential apartment buildings is estimated 150 – 250 kWh/m^2 and in public buildings 200 – 300 kWh/m^2 (CIUPD, 2015). Co-generated district heat and electricity are mainly produced with natural gas but the main share of electricity still with coal fired condensing power.

Climate Zones	Mean Monthly Temperature	
	Coldest	Hottest
Severe Cold	≤ -10 ^{0}C	≤ 25 ^{0}C
Cold	-10 - 0 ^{0}C	18-28 ^{0}C
HSCW	0- 10 ^{0}C	25 - 30 ^{0}C
HSWW	>10 ^{0}C	25 - 29 ^{0}C
Temperate	0 - 13 ^{0}F	18 - 25 ^{0}C

Figure 1. Climate zones in China (Shui & Li, 2012)

2. ChangJi regional plan

2.1 Planning process

Forests cover approximately 28% of the land area of ChangJiest. The forest areas are saved from construction. Agricultural land and forests together cover more than 50% of the total land area of about 4000 km^2. The population of ChangJi is expected to grow from the present 910 000 up to 5,1 million in less than 30 years. At the same time the widely spread out development with the isolated dwelling and job areas promote private car transport. This development has already contributed to construction of wide roads and huge parking areas; the walking distances are long and implementation of an efficient public transport is problematic.

The ChangJi planning project introduced the Finnish regional planning processes and tools to Chinese planning procedures. A Sino-Finnish group of experts from various planning and design fields analyzed the direct and indirect impacts of the plan. An environmental impact assessment tool was used for cross-evaluation of development themes and targets, Table 1. The aim of the tool is to find the needs for information and possible on-site investigations.

Table 1: Through cross-evaluation of planning themes and priority target areas in planning analyzing the environmental impacts and information were recognized that various fields needed further investigations.

Planning themes / *Planning targets*	*Descriptions for new development*	*Housing and living environment*	*Earth (soil and solid ground), water, air and climate*	*Flora and fauna, biodiversity and natural resources*	*Structure of built environment, infrastructure, energy and traffic*	*Visual image of the whole region cultural heritage, archaeology*	*Source of livelihood*	***Unsure issues and knowledge needs***
Protecting of nature								
Protecting of cultural heritage								
Water management								
Clean energy production								
Transportation network								
Recreational areas and routes								
Structure of built environment								
Further analysis and information needs								

The regional plan provides opportunities for a safe and healthy living environment that considers different population groups. Various provisions certify the protection of the built environment, landscape and natural values; and leave a sufficient number of areas for recreation.

2.2 Planning targets

The ChangJi regional land use plan takes into account the functionality, economy and ecological sustainability of the community structures. The regional land use plan bases on estimated phase-by-phase population growth. The phasing ensures the full utilization of the existing community structures.

The opportunities to re-organize traffic, especially public transport and non-motorized traffic are considered. The use of renewable energy and waste management, sufficient water supply and drainage are implemented in land use in an appropriate manner that is sustainable in terms of the environment, natural resources and economy.

The plan's impact on community structure, the built environment, nature, landscape, arrangement of traffic, especially public transportation, and technical services, economy, health, social circumstances and culture, and any other significant impacts should be analyzed. In ChangJi, the large-scale impact analysis was already carried out but the detailed information is missing. Ground water areas to be saved from construction activities and, e.g., areas with polluted land or noise pollution from road traffic should be mapped before the final regional plan.

Figure 2. The urbanization in ChangJi requires millions of square meters of new housing. New housing areas are often remote and not connected to existing towns. (Photo: Sanukka Lehtiö)

The regional plan of the area bases on development in three phases according to population growth. The 1st phase aims at construction in the existing areas for about 600 000 new inhabitants. The 2nd phase will expand the existing areas, and the 3rd phase brings completely new cities and towns into the development. This way the utilization of existing infrastructure is maximized and the distances stay short. The planning and construction will promote public transportation as the primary transport mode. The areas need to be dense enough with sufficient amount of population to support the public transportation.

A specific target is to plan a new Airport City as a landmark for the area including high-tech businesses, universities, exhibition center and residential areas.

Expansion of the existing areas may start only after the areas of the 1st phase are completed. These areas can expand the structure if the growth needs more land. The practical order of construction has to be evaluated by general planning so that the new construction strengthens the existing structure. As the development is rapid, reduction of environmental consequences gives priority for a well performing public transportation. The general planning aims also at increasing the share of renewable energy or carbon neutral energy, promotion of energy efficient buildings, sustainable use of materials and material savings, and efficient infrastructure. The development should guarantee sufficient basic services for the inhabitants (day care, school, health care, and other daily services).

Sustainable transport allows for the basic access and development needs of individuals, companies and society to be met safely and in a consistent way with regard to human and ecosystem health at the same time as it promotes equity within and between successive generations. Sustainable transport system on a large area requires co-operation with different regional and municipal actors. The ChangJi area includes both regional fast trains and slower local trains which are linked to local transport systems.

The planned sustainable transport system includes all the transport modes that are considered socially and environmentally friendly. This refers to transport modes that have low carbon emissions (close to zero) or are totally emission free. It includes walking, cycling and public transportation, but also environmentally friendly carpooling systems, car share, taxis (if low on CO2 emissions) and vehicles that cause low environmental impacts in use.

The most important route planning of the public transportation system bases on a trunk line system, where the strong public transport links form the root to the system connected to housing, work places and services. Secondly, feeder links are connected to the trunk line system. The level of connectivity depends on the planned population in different areas – the higher the population the better the connectivity. Land use planning connected to transport planning helps for the estimation of successful user levels for the public transportation, but also make the new housing areas more sustainable.

Figure 3 shows part of the regional plan as an example. The markings and symbols on the ChangJi regional plan are implemented from Finnish regional planning and general planning. Figure 4 shows an example of the expansion of existing structure. Areal markings present the various development zones and subareas for further investigation or to emphasize the further detail planning. Intended land use is presented with areal markings. Symbols are used for different sites, nodes and such land use where area need is minor. Line markings and symbols are used for roads, lines and pipes. The plan colors show the development targets (existing areas, new residential, commercial or industrial areas and other intended purpose of use. Dotted arrows show transport system development directions and, e.g., dotted circles urban development areas supported by existing public transport. Different layers in the plan include infrastructures, transportation networks waste management centers with energy production facilities etc.

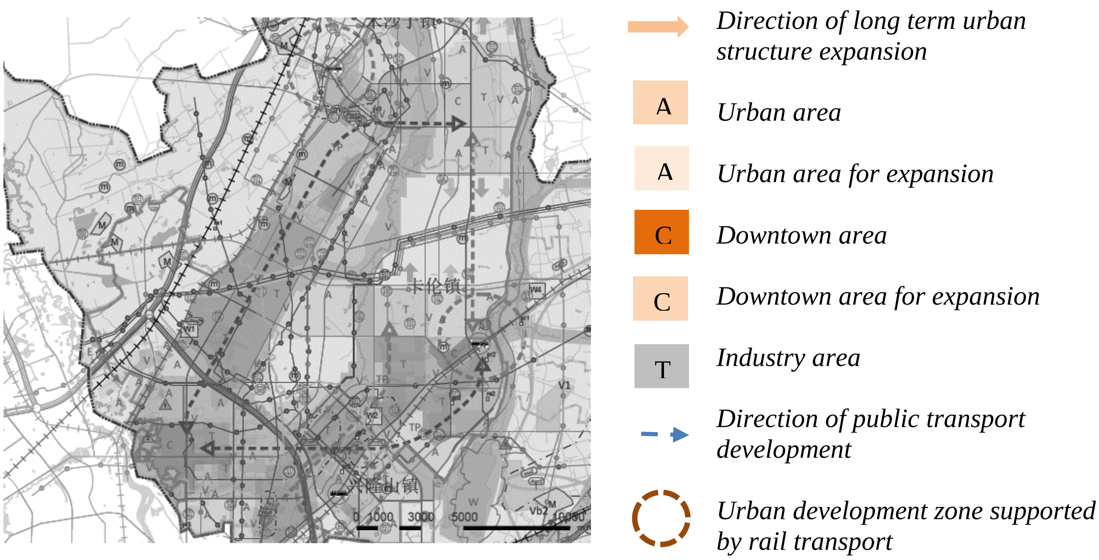

Figure 3. Example of the plan and plan markings (Architect Sanukka Lehtiö)

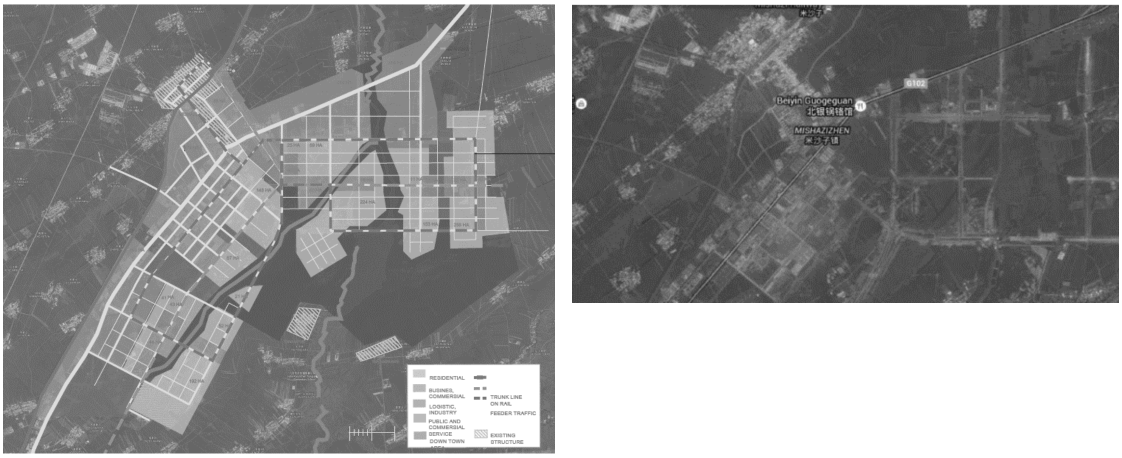

Figure 4. Planned expansion of an existing area (Architect Anna Brunow)

The target of regional level plan of ChangJi area is to be the guideline for the sustainable land use. There is a particular need to rely the strengths of each area or district in developing regional structures, to promote the creation of networks between the areas or regions, to agree on specialization, and to create particular development zones. An efficient utilization of existing structures will also improve the economy. The quality of the living environment is an important issue with a view to ecological sustainability and prevention of significant environmental damage. The volume of traffic and division into different modes of transport, energy consumption and the cost of infrastructure are largely determined by the structure on community in general planning.

3. Sustainable energy

3.1 Energy demand

The energy demand analysis of the whole ChangJi area bases on present population and estimated growth in different development phases. The population growth from 900 000 up to 5,1 million people will altogether require 170 million m^2 new residential buildings and 80 million m^2 commercial, office and public buildings. There is no exact data on building energy use available for North-East China. Therefore, reference information (collected by Paiho et al., 2013) was used for the estimations, Table 2. The energy demand of the ChangJi area excludes energy use in the industrial processes.

Building energy use in China (Paiho et al., 2013).

Energy application	*Building energy use kWh/m^2*
Rural areas	*7,5*
Northern cities for heating	*60 - 130*
Electricity use excluding heating	
• *Residential*	*10 – 30*
• *Typical public buildings*	*26 – 60*
• *Large public buildings*	*70 – 300*
• *Other*	*30*

Hot water heating Changji bases on various technologies. Residential buildings may have an apartment based electrical, natural gas water heater, or solar thermal systems. In office buildings, also separate boiler stations are used.

The total energy use (heating, cooling, electricity) excluding energy use in the industries will rise from the present 5,5 TWh up to 35 TWh. Approximately one third of the total is electricity. As the urbanization continues, household electricity use will increase more in relative terms than heating energy while the heat demand of new buildings is substantially lower than that of the present multi-story buildings. Heating season is fixed and it is presently 167 days per year. The estimate includes phase-by-phase improvement of energy efficiency of buildings and development of passive and solar districts.

Passive house is a voluntary approach to design and build an energy efficient building. There are several different definitions for a passive house in Europe. The original definition comes from Germany. The climate of Germany is quite mild compared to North-East China. The winter climate of ChangJi is comparable to Central Finland although with higher solar potential. The energy demand of a passive district or neighborhood bases on the following assumptions:

- Space heating demand 25 kWh/m^2
- Hot water heating demand 25 kWh/m^2
- Electricity demand 30 kWh/m^2.

3.2 Energy mapping

The energy plan for the district includes implementation of efficient technologies for energy production according to energy demand. There are two key issues in the energy plan: Minimized energy consumption of the district, and efficient renewable or carbon neutral production for clean energy. The energy plan includes all the energy that is needed in the district. Key element in an energy plan is energy mapping to define feasible local energy sources. The energy mapping supports the entire city design and usage process. Figure 5 shows the energy resources that can be utilized in ChangJi development.

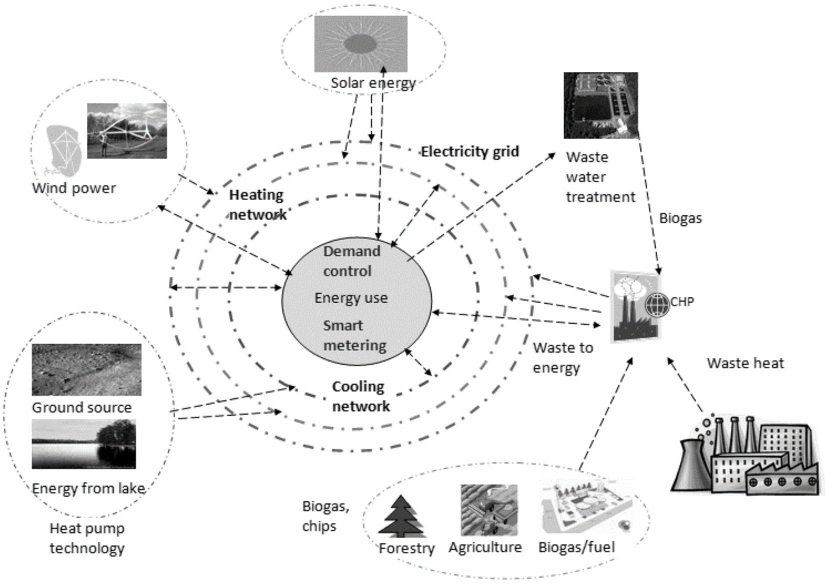

Figure 5. Feasible energy sources for ChangJi

The ChangJi energy map shows the potential sources to cover the energy demand. Basically the energy services depend on the location of the energy use, Figure 6. Rural villages and small towns are optimal for distributed energy sources whereas cities can utilize both centralized and distributed systems. The ChangJi area lacks a proper waste management system. Waste incineration is one feasible system for large-scale CHP production.

The energy services are planned for multi-source mixed energy production. The energy production scheme depends on the population of the planning area and the possibility to combine areas under a common energy system. The systems are centralised, mixed or distributed systems.

Figure 6. Energy production schemes.

3.3 Energy services

Centralised energy production bases on co-generated heat and power CHP. Environmental consequences of the production need to be reduced by renewable or low carbon fuels. In large-scale facilities, the potential fuels are municipal waste and natural gas. Natural gas is used for co-fuel in the beginning of the burning process and for improving the energy efficiency of the process. The fuels for the reference waste incineration CHP plant in Vantaa, Finland, are 44% natural gas and 56% municipal waste for production efficiency of 95%.

The potential of waste to energy for the whole Changji area is approximately 10 - 20% of the total energy demand. The share can be increased by better energy efficiency of the buildings, more efficient waste collection especially from shops and service buildings and utilization of agricultural waste. However, agricultural waste is more suitable for micro CHP systems for villages.

Waste to energy facilities can be built in the 8 waste management centres in the area. Natural gas with existing delivery infrastructure is the primary alternative and more environmentally friendly fuel as coal. Coal fired condensing boiler power plants are the most inefficient power production facilities. These production facilities have efficiencies between 30 and 40%. CO2 emissions from the old Chinese production plants vary from 800 kg/MWh up to 1600 kg/MWh. The typical existing Chinese CHP facilities have efficiencies between 60 and 80%. A modern waste to energy CHP has an efficiency of 90 – 95% and thus would reduce emissions from energy production drastically.

The purpose of mixed energy production is to utilize multiple sources of energy in addition to large-scale production facilities. These combinations are suitable for towns and villages for improvement of energy infrastructure or for small villages to cover the whole energy demand. Such systems include:

- MicroCHP for power and heat
- Ground source energy for heating and cooling
- Water source energy for heating and cooling
- Solar power for electricity
- Solar thermal as stand-alone systems or integrated to district heating
- Wind power

The wind conditions in the region do not support large-scale wind power. Therefore, only local systems with capacities below 10 kW are feasible.

There is a wide range of microCHP systems with capacities for 3 – 3000 kW electricity and 15 – 12000 kW heat. Typical agricultural wastes in the region are corn stalk, straw and husk with an average energy content of 4 – 5 kWh/kg. Total amount of the residues for energy production is estimated 400000 – 500000 tonnes.

Ground source energy can be used for single buildings, group of buildings or as local district heating and cooling system. Typically, the system runs with heat pumps but it can serve as an energy storage as well. Figure 6 shows a principle of heat pump heating and cooling system for an apartment building. There are six heat well bored down to 200 m in the ground. The heat wells are located with 15 m distances for to prevent disturbance between the wells.

Water source or combined water and ground source system are feasible as well, Figures 7 and 8. Heat exchangers either at the bottom of a lake or on the ground can be used in water source. Water filled abandoned coalmine shafts can be used for heat storage and water source heating and cooling.

Solar power (PV) system varies from Building integrated PV to large solar power plants. Solar power can serve as distributed system for all developments. It are especially usable for cooling, as the load match is perfect.

Figure 7. Heat pump heating and cooling

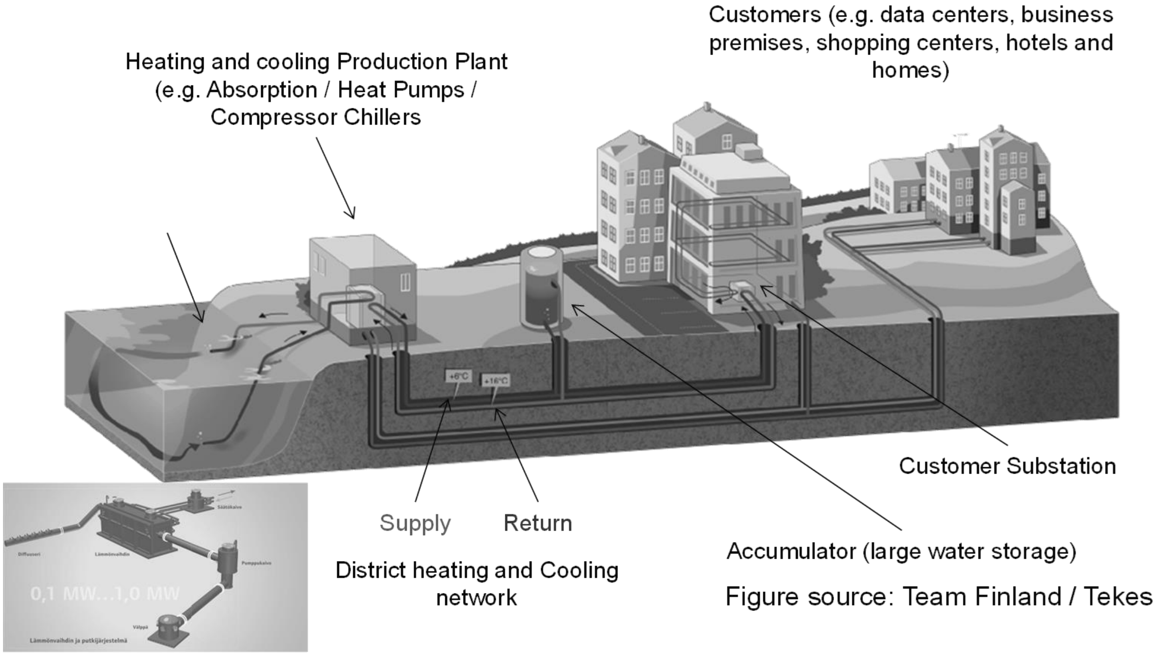

Figure 8. Water source heat pump heating and cooling

4. Conclusions

The first phase of the project produced models for further development. The environmental and economic targets set for the region are high surpassing the requirements set by the legislation and typical planning projects. Especially the to be planned Airport City can serve as a world-class example of Chinese ways and means to develop sustainable cities.

The risks involved in the development is the typical Chinese scheduling of projects and lacking knowhow in implementation of the various technologies. The hard-pressed progress may bypass the targets. It also inevitable that the city planners need to connect with technology providers and specialists to avoid misinterpretation in implementation of technologies.

Abstract

As many of us live in apartment buildings, we all know that the stairways are noisy and reverberant thus disturbing the residents. Currently, no study is available to show how the amount and positioning of attenuating material in stairways impacts on the acoustic environment of apartment blocks. This study demonstrates the effect of a two stage acoustic treatment carried out in a four-storey apartment building. Measurements and sound samples were taken at three separate stages to describe the development of acoustics: before, stage one and stage two. Before: no absorption. Stage one: A-Class sound absorption material was installed on the ceilings. Stage two: sound absorption tiles were added to the underside of the staircases. Measurements tell about very significant improvements in the stairway: Reverberation time (T20) shortened by 3 seconds from 3.6 to 0.6, Speech Transmission Index (STI) increased from 0.47 to 0.81 and Sound Pressure Level decreased by 10 dB. Additionally, the sound samples recorded at each stage revealed a huge change. From these results we can conclude, that this acoustical treatment was really worth doing. The stairway is now more peaceful, harmonious and makes the residents` lives feel a bit more luxurious.

Keywords: Acoustics, room acoustics, sound absorption, stairway noise, apartment building

1. Introduction

Many of us live in apartment buildings knowing, that the stairways are noisy and reverberant thus disturbing the residents. Currently, no study is available to show how the amount and positioning of absorption material in stairways impacts the acoustic environment of apartment blocks.

The purpose of this study, with acoustical measurements and sound samples, is to give useful information to housing companies and builders, how to make noisy stairways quieter and the residents satisfied. Furthermore, the measurements taken at three separate stages, tell us also how the sound absorption material affected the acoustical parameters.

This study and acoustical measurements were carried out in a housing cooperative Hakanmetsä, in Helsinki at 2014.

2. Measurements and sound samples

Measurements and sound samples were taken at three separate stages:

- before (no absorption)
- stage 1 (absorption on the ceilings)
- stage 2 (absorption tiles were added also to the underside of the staircases)

At stage 1 and 2 the room acoustical parameters were measured on two separate floors. The measurements were taken according to SFS-EN ISO 3382 [1-3] and IEC 60268-16 [4] standard.

At stage 1 (Figure 1) 28 m2 (which was also the entire surface area) of impact resistant A-Class sound absorption material (Ecophon Super G 35 mm) was installed on the ceilings of each landing. The ceiling was installed with suspension of 100 mm (overall depth of system, ods).

At stage 2 (Figure 1) the sound absorption tiles (Ecophon Super G 35 mm) were added 12 m2 (the entire surface area was 18 m2) to the underside of the staircases.

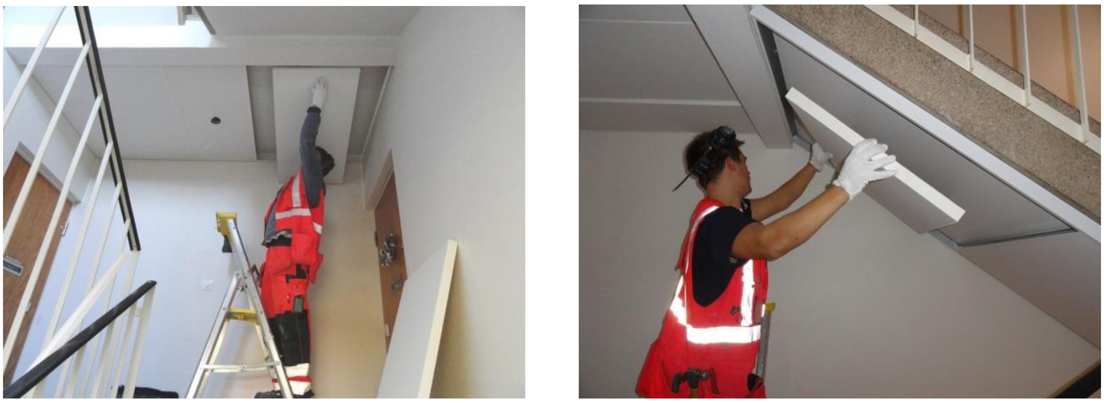

Figure 1: At stage 1 A-Class sound absorption material was installed on the ceilings (left) and at stage 2 sound absorption tiles were added to the underside of the staircases (right).

The measurements were performed by using impulse response method (test signal log-sweep, 10 s, 2 source and 6 microphone positions at each floor). The following acoustical parameters were calculated in octave bands (63 Hz – 8000 Hz) from measured impulse responses:

- Reverberation Time, T20(s)
- Sound Pressure Level, LAeq (dB)

- Speech Transmission Index, STI (values between 0 -1)

Speech Transmission Index value of 1 means that speech is perfectly intelligible. The closer the STI value approaches zero, the more information is lost.

In addition the Sound Pressure Level passing through the door from the stairway into the apartment, was measured at each stage by using reference noise (pink noise, LwA= 92,0 dB).

The sound samples in the stairway were digitally recorded (Olympus LS-5). Recorded samples were typical sounds in everyday life such as noisy children and a woman coming downstairs with high heel boots on. Additionally one sample was recorded by using a short sentence which was recorded earlier in an anechoic chamber. Then that sentence was played back in the stairway with Genelec 6010A loudspeaker and recorded at each stage like all sound samples were.

3. Measurement results

Figures 2 and 3 describe Reverberation Time T20 (s), figure 4 shows Speech Transmission Index (STI) and tables 1, 2 and 3 describe Sound Pressure Levels in different microphone positions. The stairway`s background noise level during measurements varied between LAeq = 30 – 35 dB.

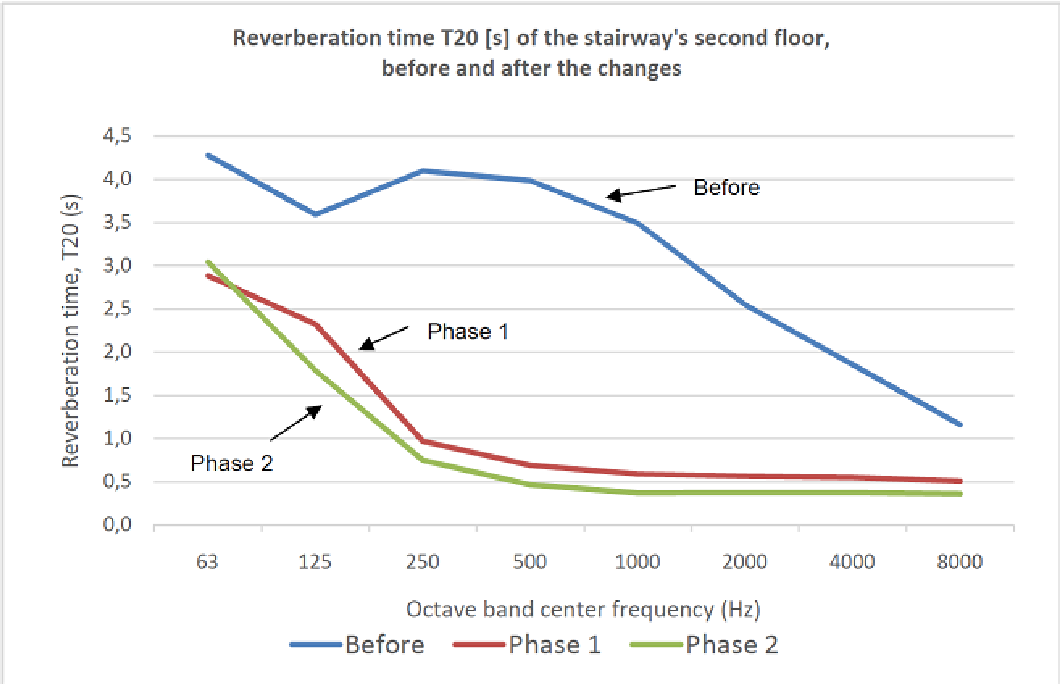

Figure 2. Reverberation Time T20 (s), (63 Hz – 8000 Hz) before and after each stage.

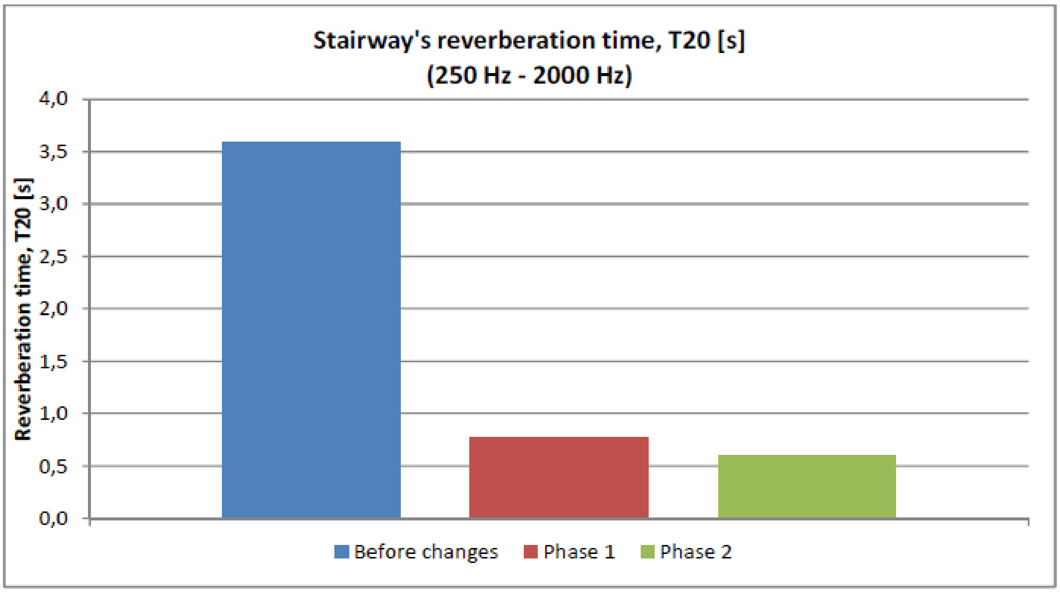

Figure 3. Reverberation Time T20 (s), (250 Hz – 2000 Hz) before and after.

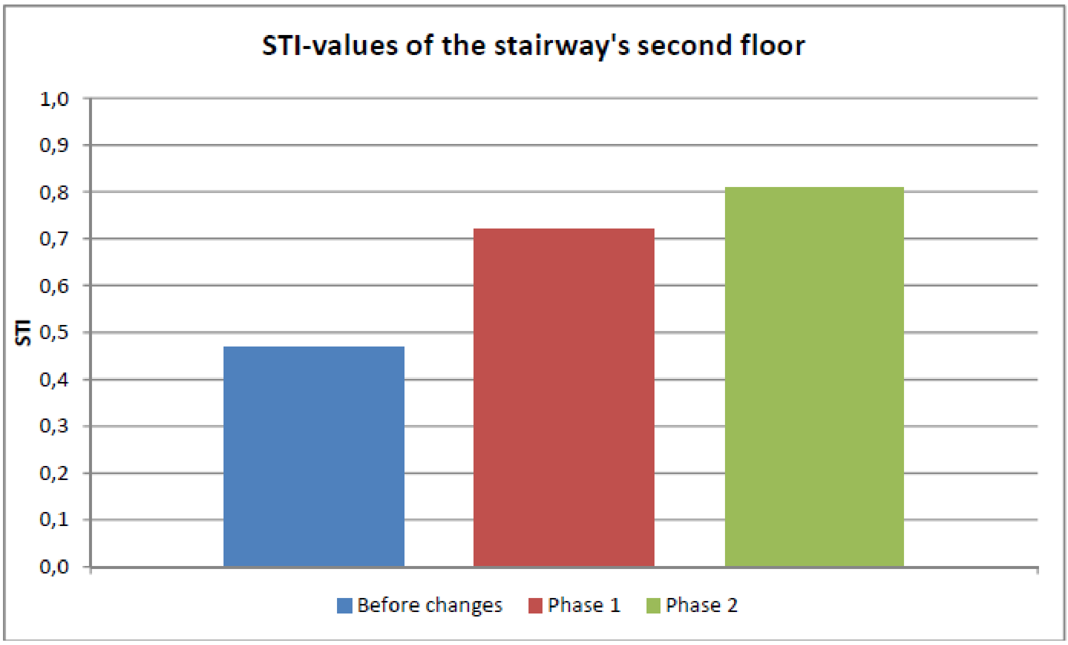

Figure 4. STI - values before and after.

Microphone position	Sound pressure level, $L_{A,eq}$ [dB]		
	Before	Phase 1	Phase 2
Floor 1.5	90	83	81
Floor 2.5	90	83	80

Table 1. Sound pressure levels of the reference noise (LwA = 92 dB). Loudspeaker is on the 2nd floor.

Microphone position	Sound pressure level, $L_{A,eq}$ [dB]		
	Before	Phase 1	Phase 2
Floor 4	80	63	57

Table 2. Sound pressure levels of the reference noise (LwA = 92 dB) at the top floor, when loudspeaker was on the ground floor.

Microphone position	Sound pressure level, $L_{A,eq}$ [dB]		
	Before	Phase 1	Phase 2
Floor 3	91	81	81
Floor 4	93	84	83
Inside an apartment (2nd floor), outer door closed, inner door open	61	48	45

Table 3. Sound pressure levels of the reference noise (LwA = 92 dB). Loudspeaker is on the 3.5 floor.

Space	Reverberation time, see tables 1-3 and 5-7	The National Building Code of Finland, part C1:1998 requirement (500Hz - 4000Hz)
Stairway, before	Does not fulfill the requirements	≤ 1.3 s
Stairway, phase 1	Fulfills the requirements	≤ 1.3 s
Stairway, phase 2	Fulfills the requirements	≤ 1.3 s

Table 4. The measured reverberation times are compared to the requirements of the National Building Code of Finland, part C1:1998 [5].

4. Discussion

In figures 3 and 4 we can see the biggest change occurred in phase 1. Before changes the Reverberation time was 3.6 seconds, after Phase 1 it was 0.8 s. and after Phase 2 it was 0.6 s. Owing to dramatically shortened Reverberation Time, whenever noise comes up in the stairway, it will almost immediately fade out as well.

Figure 4 diagram prooves out that adding absorption enhances also the STI-value. This means improved speech clarity. Thanks to that, whenever people meet in the stairway, they start to talk with a lower sound level than they did earlier. And as a consequence, talking in the stairway is hardly audible anymore inside the apartment.

Table 1 demonstrates that after phase 1 the sound pressure level decreased 7 dB and after phase 2 it dropped 3 dB more, altogether 10 dB. This is such a big reduction, that people experience the sound strength only as half what it was earlier.

From Table 2 we can see that after phase 1 the sound pressure level from ground floor to floor 4 decreased 17 dB, which is really huge reduction. After phase 2 the sound pressure level dropped still 6 dB more, so the total reduction was as much as 23 dB.

Table 3 shows clearly, that absorption material decreases effectively the sounds coming from the stairway inside the apartment. After phase 2 the sound pressure level dropped even 16 dB.

In table 4 we can see that the reverberation time meets the requirements of the National Building Code of Finland already after phase 1.

5. Conclusions

From these results we can conclude, that this acoustical treatment was really worth doing and meets the requirements of Finnish National Building Code, C1:1998 even after stage 1. The sound absorption, which was installed on the ceilings of each landing, already gave the residents good protection from noise coming from stairways. But undoubtedly, adding the sound absorption tiles also under the staircases decreased the noise disturbance even more, thus making living in the apartment flats even more peaceful.

The stairway is now more comfortable, harmonious and makes the residents` lives feel a bit more luxurious in this noisy world we are living in.

The Development of a Generic Design for Primary Healthcare Facilities in South Africa

Llewellyn van Wyk, Peta de Jager and Theunis Knoetze

CSIR Built Environment, South Africa
lvwyk@csir.co.za

Abstract

Primary healthcare (PHC) service delivery is severely hampered by lack of, and poor quality infrastructure. In many cases the physical infrastructure at clinics is old, inadequate and in some cases not suitable for use. The provision of services (water, sanitation and electricity) is in many cases not adequate, especially in rural areas. This study developed a generic design for modular conventional clinics and for rapid deployment clinics. Researched, patient-centric service delivery and workflow have been used as major drivers for design configuration. Clinics have been organised to accommodate three patient streams: namely chronic services, acute services, preventive and promotive services. An optimal patient flow pattern was determined and the infrastructure norms and standard guidelines developed by the South African National Department of Health were considered. The space requirements were derived from the design terms of reference and the PHC norms and standards. Two methods of construction were assumed, i.e. traditional brick and mortar, and Innovative Building Technology (IBT) system with the latter being an insulated panelised system. A conceptual design for a generic, basic clinic for use in South Africa is developed. The conceptual design is modular based and allows for additional functions to be added as and when required. The design is both flexible and adaptable. It is highly likely that the clinic may function off-grid under certain circumstances.

Keywords: health infrastructure, basic clinic, building services

1. Introduction

Recognising that historical funding models have entrenched inequity and undermined affordability of healthcare services in South Africa, the South African National Department of Health has introduced the National Health Insurance (NHI) scheme to integrate healthcare services. This requires a "re-engineered approach to providing primary health care (PHC) using a population based approach for the delivery of PHC outreach service to the uninsured population of South Africa" (NDoH 2011:2). Major implications, such as shifting to increased community outreach services (as opposed to facility-based services), and emerging requirements for information networks (for NHI management) are foreseen. As infrastructure is integral to the delivery of healthcare services, these organisational transformations provide an extraordinary opportunity for science, engineering and technology input across the life cycle of primary healthcare facilities.

Primary healthcare (PHC) service delivery is severely hampered by lack of, and poor quality infrastructure. In many cases the physical infrastructure at clinics is old, inadequate and in some cases not suitable for use. The provision of services (water, sanitation and electricity) is in many cases not adequate, especially in rural areas. In addition to this, no standardised clinic design and lifecycle management tools currently exist. This results in poor infrastructural investment decision making, problematic procurement processes and practices and poor maintenance of existing facilities. Re-engineering of primary healthcare as the main mechanism of healthcare service delivery requires urgent intervention at the infrastructure level.

This study developed a generic design for modular conventional clinics and for rapid deployment clinics. The study does not evaluate materials that could be used or undertake a comparative analysis between materials. This study focuses on the components underlined in Chapter 3.

2. Research approach and methodology

Designers of buildings are often unable to explain how they arrived at a design solution beyond "that his or her reason for making a particular design decision is based on a 'feeling' or 'intuition'" (Wiggins 1989:1). However, increasing building complexity and sustainability imperatives require a "new decision model" (Mendler and Odell 2000:19; CIB 2009:4). Mendler and Odell (2009:24) argue that this new approach "requires some focused research time" and that sustainable design "requires the design team to consider a larger number of issues in the decision-making process" with "supplemental research to understand the environmental impacts associated with design options and to identify preferred approaches". It can be argued that what is being proposed is the use of grounded theory being "a set of rigorous research procedures leading to the emergence of conceptual categories" which may make use of both quantitative and qualitative data (GTI 2015).

The research approach to the study was based on the South African Institute of Architects (SAIA) *Plan of Work* as proposed in their Practice Manual (SAIA 1.1211:3). The Plan of Work consists of five work stages namely:

Stage 0 – Inception briefing and appointment of consultants
Stage 1 – Appraisal and definition of the project
Stage 2 – Design concept
Stage 3 – Design development
Stage 4 – Technical documentation and approvals
Stage 5 – Contract and administration and inspections

This study includes only Stages 1 and 2.

A reading of the practice manual Plan of Work may suggest that the two work stages actually imply a research-based approach to design: however the text is biased towards meeting the programmatic goals of the client rather than researching the full range of performance requirements of the building project.

The research method used by the study is Ernst Neufert: Architects' Data (ed. Herz, 1970) as it suggests a methodology closer to research-based design and uses qualitative and quantitative research data. In the section appropriately titled 'Design Method' (Herz, 1970:30) it is recommended that the “work starts with the preparation of an exhaustive brief” and lists information that must be known before planning begins. The required information includes site (location, environment, size, levels, services, fixtures); space requirements (areas, heights, positioning and relationship); dimensions of existing furniture; finance (site acquisition, legal fees, mortgages, etc.,); proposed method of construction (brick, frame construction, sloping roof, flat roof); and all the legal facts. A questionnaire is included in this approach which includes questions relating to the client, fees and agreements, persons and firms connected with the project, general, project, basic design factors, technical fact finding, records and preliminary investigations, preliminaries, and activities and events. The question is a combination of quantitative data (e.g., type of topsoil) and qualitative (e.g., what is the attitude of the town planning officer towards architecture).

It then recommends that the individual units are analysed, drawn to scale and put provisionally into groups. The relationships of rooms to each other and to the sun are analysed (Herz 1970:30). What follows is critical: ‘at this stage an “idea” in 3-dimensions will emerge’ and ‘instead of starting to design at this stage, explore the various means of access, the prevailing wind, tree growth, contours, aspect, neighbourhood, then finalise the positioning of your building, relating it to tentative landscaping, etc.’ Finally, it recommends that one ‘try out several solutions to explore all possibilities and use their pros and cons for searching examination.’ Based on the foregoing it argues that the ‘idea now becomes clearer and the real picture of the building emerges’.

What is described in Neufert’s text is grounded theory, a research method that aims to allow the theory (in this case the idea) to emerge from the research. In fact, an early attempt to ‘design’ is discouraged to allow theory testing to be done from which a ‘design’ emerges. Further evidence to support this theory is found later: Neufert recommends that after the completion of the preliminary design a pause is taken to ‘help get rid of preconceived ideas and undigested brain-waves, and to allow time for other short-comings of the design to be revealed not least in discussions with staff and client’ (Herz 1970:30).

To further aid this research method Barry’s Introduction to Construction of Buildings (Emmitt and Gorse, 2005) is used to construct a useful methodology for considering the construction of buildings by breaking the construction process down into five basic components, namely; sub-structure, super-structure, roof assembly, services, and finishes. Each of these components can be further sub-divided into sub-components such as windows and doors for super-structure. This approach has been used with some success in previous experimental studies undertaken by the CSIR at its Innovation Site in Pretoria (van Wyk, 2009; de Villiers 2011).

3. Research question and sub-questions

The primary research question is the following:

How and in what way can Science, Engineering and Technology (SET) give input into the development of a <u>standardised design terms of reference</u>, based on a <u>modular approach</u>, for a basic clinic that will comply with primary healthcare (PHC) <u>norms and standards</u> while delivering improvements in indoor environmental quality, reductions in <u>non-renewable resource use</u>, improved construction quality, reduced construction time, reduced construction cost, and support resilient human settlements in a sustainable and economical manner?

In order to answer the primary research question, a number of sub-questions must be answered. Not all of these sub-questions are addressed in this paper: the sub-questions addressed in this paper are underlined in the primary research question.

4. Standardised design terms of reference

Researched, patient-centric service delivery and workflow have been used as major drivers for design configuration. Clinics have been organised to accommodate three patient streams: namely chronic services, acute services, preventive and promotive services. Care is taken to provide general zoning which allows for future expansion, particularly for specialised services, community outreach services, and the patient streams, where greatest future growth is anticipated.

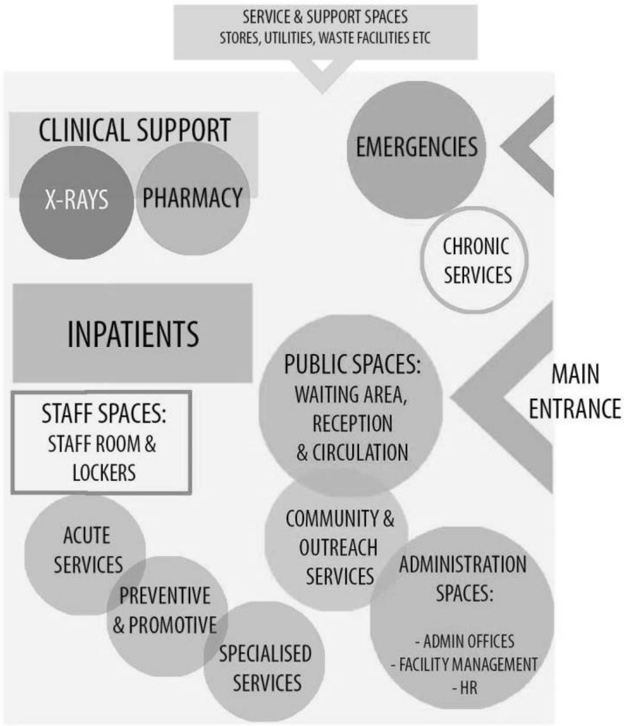

Figure 1: General zoning

4.1 General ambulant patients

Patients enter the clinic site through a controlled entrance at the security guardhouse. From here they proceed to the front entrance of the clinic building. Upon entering, patients are triaged and except for emergency cases, register at the front reception desk. Thereafter they remain in the main waiting area until called by the nurse who, where necessary, takes the patients' details, blood pressure and possibly their weight. Patients required to give a urine sample for testing will use the universally accessible ablution facility adjacent to the sample room. Having been attended to by the nurse, patients are directed to wait in the sub waiting area before proceeding to the relevant room. After consultation or counselling, patients either go to the treatment room for further assistance, collect medication from the dispensary or leave the building.

4.2 Emergency patients

Patients requiring urgent care are triaged on arrival and are immediately directed to the emergency room where they are attended to by the nurse who may arrange to transfer the patient to a referral hospital.

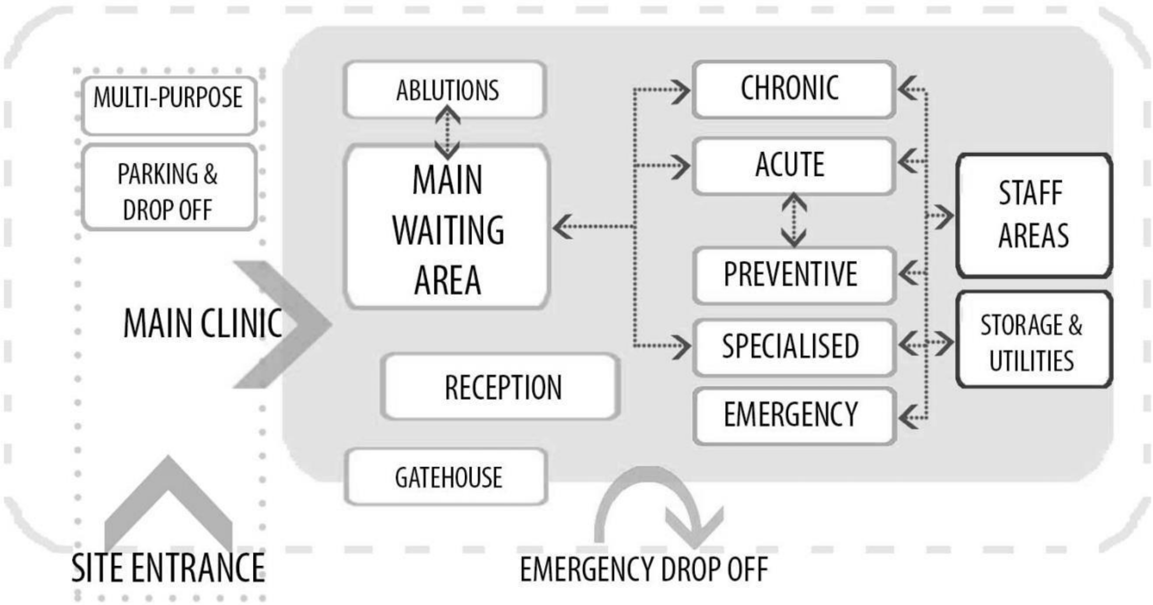

Figure 2: Functional Relationships for Basic Clinic

5. Norms and Standards

The development of guidelines, norms and standards formed part of a National Department of Health project called Infrastructure Unit Systems Support (IUSS Project). IUSS was a structured collaboration between the National Department of Health (NDoH), the Development Bank of Southern Africa (DBSA), the Council for Scientific and Industrial Research (CSIR), and other stakeholders with the shared objective of optimizing the acquisition and management of South Africa’s public healthcare infrastructure throughout the infrastructure’s lifecycle.

The development of guidelines, norms and standards has been structured into work package sets and 45 work packages including facilities and departments, regulations, engineering services, infection prevention and control, equipment, sustainability and environment, tomorrow’s healthcare environments, have been identified. A development programme has been initiated providing for input focused workshops and output focused task groups developing new draft documents.

The draft norms and standards developed for the IUSS Project have been used to prepare the concept design.

6. Modular requirements

The intention is to develop a generic basic clinic design that can be constructed using either conventional building technology (brick and mortar) or innovative building technologies (IBTs).

In both instances use has been made of a modular approach based on a modular dimension (modules of 300 mm) creating a standardised unit capable of being fitted out to serve the specific function, and have interchangeable components (doors, windows, etc.). This approach was taken to ensure that the clinic was flexible enough to adapt to local conditions and could be scaled-up to meet local needs over time. The modular approach was also applied to the design and selection of off-grid utility services, especially electricity generation (solar and wind) and sanitation.

Having regard for the patient flow and norms and standards a modular dimension of 4.2m x 3.0m created the most flexibility. In the conventional building technology application the foundations will be conventional concrete foundations and slab: for the IBT application a steel chassis will be constructed with steel supporting super-structure and roof. The IBT module will be manufactured in the factory and transported to the site where it will be placed on supporting stub columns (brick or concrete).

In both IBT cases the interior can be equipped according to its intended use either off-site, or on-site, depending on the circumstances of the specific project.

7. Non-renewable resource reduction

Buildings and their operations depend on the continued supply of services such as water, sanitation and electricity. However, service delivery failures do occur whether due to design and operational factors such as regular maintenance or system failure. An assessment of infrastructure in South Africa in 2011 noted that “the quality and reliability of basic infrastructure serving the majority of our citizens is poor and, in many places, getting worse” (SAICE 2011:5). Of the three services targeted in the study namely, electricity, water and sanitation, the infrastructure report card finds that there has been “further deterioration in the ageing bulk water infrastructure portfolio as a result of insufficient maintenance and neglect of ongoing capital renewal” with water quality identified as “a serious problem, especially outside metros” (SAICE 2011:6), “serious problems with management of many waste water (sewage) treatment works” including “waste water leakage and spillage, especially into major rivers” and that the backlog in sanitation “increasing owing to unsustainable infrastructure”, and with regard to electricity that “in many areas infrastructure is ageing and/or overloaded” with municipal infrastructure in particular described as “below standard and poorly maintained (SAICE 2011:8).

Critical services such as primary healthcare rely on a stable service provision especially with regard to water, sanitation, electricity and the proper storage of drugs. Innovative infrastructure service technologies are technologies that can be implemented to provide alternative methods for securing a stable infrastructure service.

One of the strategies that can be employed to ensure an uninterrupted service is to reduce the building’s exposure to municipal services through the use of innovative infrastructure technologies. This has a number of benefits: first, it assists the building to adapt to major perturbations and events without a disruption in service delivery; second, reducing the building’s dependence on municipal services also reduces the operational costs of the building; and third, innovative infrastructure technologies are less resource intensive, especially with regard to the water/energy nexus, as they operate at the site of use, thereby reducing the requirement to move bulk services around.

7.1 Energy

It is intended that all the power required to operate the building should be generated on site allowing the building to function off-grid. As the building is to be used primarily as a clinic facility, the design demand should be calculated on maximum demand when the building is being fully utilised. Based on an analysis of the expected demand for electricity, a load profile was generated using the expected utilisation of appliances. The daily average power consumption of the clinic was calculated as 19,8kWh/day, i.e., an electricity generation system that is sized to produce 20kWh/day is required. The cost of a 20 kWh/day PV system for a sunny but wind poor location such as CSIR Pretoria campus ranges from R291,718.00 to R319,000.00 inclusive of VAT and requires 48m^2 of PV panels. The cost of a 20 kWh/day wind system for a windy location such as the East London Industrial Development Zone is R287,854.56 inclusive of VAT and requires 2 x 3kW wind turbines. Preliminary investigations indicate that a wind system is slightly cheaper than a PV only system, but is site dependent on the availability of wind and solar resources.

The following three options were recommended, each one capable of being up-scaled using the modular approach, for the clinic to function off-grid:

- Photovoltaic (PV) based system for the generation of electricity for sunny but wind free sites such as CSIR Pretoria campus.
- Wind based system for the generation of electricity for windy sites such as the East London Industrial Development Zone.
- Liquid Petroleum Gas (LPG) for heating and cooking.

7.2 Water

Standard setting for water and sanitation at clinics takes place within specific dimensions of quality - acceptability, accessibility, appropriateness, continuity, effectiveness, efficiency, equity, interpersonal relations, technical competence and safety. Different kinds of facilities will be required to provide the same services in different situations, for example services to clinics in remote rural areas will be provided through different facilities compared to polyclinics in high-density urban areas. Therefore national standards about facilities and staffing norms for clinics are not set. The National Department of Health defines what services and facilities are required to best meet the health needs of the nation, i.e. a clinic must have a supply of electricity, running potable water and proper sanitation, which means adequate number of toilets for staff and users in working order and accessible to wheelchairs, but do not specify how the services are to be provided and at what level the standards should be met.

Clinics, especially in rural areas, tend to become a social gathering point for the communities, mainly because of the general lack of infrastructure (electricity, water sanitation, roads, transport, etc) compared to clinics in urban areas. The person-load per day of rural clinics is therefore generally higher than that of urban clinics, as patients normally have the responsibility of caring for a number of children/family, or are too old, or disabled, to visit the clinic by themselves and need assistance, and as transport services are infrequent, long waiting periods.

Water conservation includes rainwater harvesting and treatment, and waste water recycling systems. Rainwater harvesting, in its essence, is the collection, conveyance and storage of rainwater. The scope, method, technologies, system complexity, purpose and end use vary from rain barrels for garden irrigation in urban areas, to large-scale collection of rainwater for all domestic uses.

In the case of this clinic design, rainwater is collected and stored in rainwater tanks: the tank or tanks can either be positioned on the ground close to the downpipes or in a single more ideally situated location, or buried in the ground as a subterranean tank. The number of people being served at the proposed clinic estimated at 1400 per month. The recommended water allowance per person per day use as recommended in the World Health Organization guidelines is 2 to 6l/d (WHO 2011:9.2). The water demand per month will range between a lower limit (1400 x 2 x 22 = 61600) and the upper limit (1400 x 6 x 22 = 184800). No provision is made for urinals and the water closets (wc's) are based on closed-system units described more fully under sanitation. Using Pretoria as the location of the clinic, and given the area of the building (300 m^2) and the annual rainfall (732mm) (Climatemps 2015) the expected maximum annual harvested water supply will be 219600 liters which is insufficient to meet the needs of the clinic. Additional water sources will be required including sustainable urban drainage systems (SUDS) which will be very site-specific.

7.3 Sanitation

Lack of sanitation in healthcare facilities appears to be a more serious matter than lack of water supply. Many factors influence the choice of sanitation technology that meets the requirements for adequate sanitation at clinics, and these include:

- Cost effective provision of services and accessible to maintenance and servicing of the toilet by local community members.
- Management - The choice of system that is sustainable over the years.
- Use of the local contractors targeting youth and women.
- Sustainability of employment for the operation and maintenance.
- Improvements to health.

If a water supply is available, a conventional water-borne system can be selected, but many rural clinics have an erratic water supply that is inappropriate for the provision of water-borne sewage systems. In the case of insufficient water supply the choice of sanitation facility is usually limited to a dry on-site system, whether a VIP or waterless system, or a closed-loop recycling system. On-site, close-loop system, flush toilet waterborne sanitation systems are available from a number of companies and manufacturers in South Africa. They are ideal sanitation solutions in cases where only dry sanitation was an option. Generally in these systems naturally-occurring micro-organisms (bacteria) are selected as a biological additive to the digester tank. The biological process occurring in the digester tank converts raw sewage into re-usable filtered water, ready for re-use to the toilet cistern for flushing. A solar panel is installed to power the recycle pump in the digester unit. The product can be supplied as a pre-assembled unit or it can be supplied in a kit form to be assembled on site. This makes the transport of the unit much easier and no heavy equipment is needed for installation. The parts can easily be handled and carried by hand.

8. Concept design

From the above data a concept design was generated. Using the design approach advocated by Neufert (Herz 1970:30), the design commenced by the preparation of an "exhaustive brief". This was obtained from the patient flows and the PHC norms and standards. No specific site was identified so the assumption was made that the site is accessible on all sides, is flat, and is north orientated. It was assumed that no services are available. The space requirements were derived from the design terms of reference and the PHC norms and standards. It was assumed that finance would be made available from Government. Two methods of construction were assumed, i.e. traditional brick and mortar, and Innovative Building Technology (IBT) system with the latter being an insulated panelised system.

The second phase of the concept design analysed all the individual units, drew these to scale, and arranged them in groups (see the plan sketch in Figure 3). From the 2-dimensional floor plan a section was generated (see section in Figure 2). This was the outcome of a number of “solutions to explore all possibilities and use their pros and cons for searching examination” (Herz 1970:30). A number of assumptions were used to generate the section. First, the building is raised to enable displacement ventilation to occur. An overarching roof was generated to provide additional shade to the rooms below, and to enable the extraction of air from the rooms. Preliminary ideas around the fitting of photovoltaic panels and solar water heaters are explored, as well the fitting of a rainwater harvesting system. The potential to open and shut the rooms is also explored to aid ventilation and security after hours. The section was the first attempt of a “real picture of the building emerging”. From the plan and the section a 3-dimensional sketch could be generated (see Figure 3).

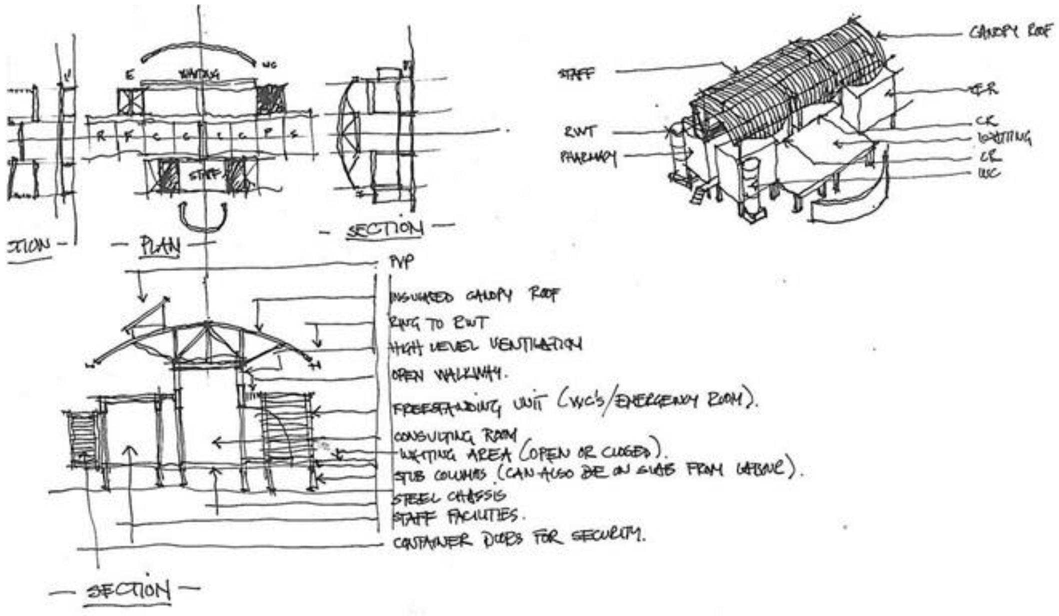

Figure 3: Design sketch

As already indicated above, this sketch was the outcome of a number of iterations. Further to Neufert, “a pause is taken to help rid of preconceived ideas and undigested brain-waves, and to allow time for other short-comings of the design to be revealed not least in discussions with staff and client (Hertz 1970:30).

The outcome of this period of reflection was the further development of the design as shown in Figure 4.

Figure 4: Conceptual design for basic clinic

9. Conclusion

The study developed the basis for a generic basic clinic for application in South Africa. The conceptual design is modular based and could be constructed using either conventional building technologies (brick and mortar) or Innovative Building Technologies (IBTs). The conceptual design also allows for additional functions and its supporting infrastructure to be added as and when required. The design is therefore both flexible (the modularity allows rooms to be used for different functions should the requirements and needs change) and adaptable (may be extended in a number of ways).

The research finds that it is highly likely that the clinic may function off-grid under certain circumstances with the exception of water where approximately half of the required demand can be met off-grid. These circumstances relate to climatic conditions, topography of the site, location of the site, ground conditions, and the extent of the site.

Modelling the Process of Innovation in Construction: Framework and Research Agenda

Bismark Duodu and Steve Rowlinson

Dept. of Real Estate & Construction, University of Hong Kong, Hong Kong
Email: bduodu@hku.hk

Abstract

Increasing demand and expectations from clients coupled with the need to compete necessitate that Construction firms innovate to gain competitive advantage. Despite the labelling of the construction industry as less innovative by a number of reviews and comparative studies, innovation in the industry occurs at a high rate often hidden on projects. A better understanding of such innovation processes could be crucial for the management and implementation of innovations. However, current innovation literature in construction is focused on adoption and diffusion of innovations sourced from manufacturers and leading suppliers. Attempts at innovation processes have often come from generic models of how innovation occurs in construction based on theoretical speculation rather than empirical observation of the processes of specific innovations. This has resulted in a lack of understanding of the dynamics and processes by which innovation occurs in construction and an inadequate process theory for construction innovation. This paper presents a framework and agenda for exploring the trajectory of innovations in construction adapting concepts from the Minnesota innovation studies framework (MISF). The MISF suggests that the process of innovation involve five concepts: ideas, people, transactions, context, process and outcomes. The paper also draws on organizational ambidexterity theory and the intellectual capital based view, proposing a framework that is an adaptation of MISF. The proposed framework focuses on innovative ideas as being explorative or exploitative; people in terms of human capital; transactions shaped by social capital and context as organizational capital; the process as the sequence or stages of innovation generation or adoption for implementation and outcomes as the consequences of the innovation process for projects and firms. The paper draws on an ongoing research that aims to develop process theory for construction innovation, which can potentially provide a model of the innovation process in construction based on real examples of how processes of specific innovations unfold.

Keywords: Innovation Process, Construction Innovation, exploration, exploitation

1. Introduction

The construction industry has been described as an important sector contributing significantly to the socio-economic development of nations. However, the industry has been criticized for its poor performance (Harty, 2008; Winch, 1998). The answer to the industry's challenges is considered to lie in the development of a stronger innovative culture to improve the rate and quality of innovation across the industry (Harty, 2008; Manley, 2008). The unique nature of projects necessitates that construction firms explore new innovative solutions or exploit existing capabilities to solve problems. However, knowledge of the processes of exploration and exploitation of innovative ideas in construction is limited. Most studies on exploration and exploitation have been conducted in high technology intensive industries (e.g. He & Wong, 2004; Katila & Ahuja, 2002) with a few exceptions (e.g. Liu et al., 2012) that have investigated project based firms or project settings.

Mainstream innovation researchers have proposed numerous stage-based models to represent the innovation process as a sequence of discrete steps or stages (e.g. Rogers, 1983; Zaltman et al., 1973). These models, however, lack an empirical basis and there have been a few attempts to test the ability of such models to reflect how innovations develop in real situations. The innovation process has been described to be very much fluid than such stage models suggests, and in the project based environment can be very interactive and dynamic with feedback loops (Manley, 2008). Similarly, current literature on construction innovation processes is mostly generic models (e.g. Gann & Salter, 2000; Slaughter, 2000; Winch, 1998) of how innovation occurs in construction. These are based on theoretical speculation rather than empirical observation of the processes of specific innovations. This has resulted in a lack of understanding of the dynamics and processes by which innovations occur in construction and an inadequate process theory to help better manage the innovation process.

Among the central problems in the management of innovation according to Van de Ven (1986) is the process involved in the management of ideas into good currency to ensure implementation. Innovation efforts in the industry are considered to be disproportionately oriented towards enhancing products rather than process improvements. This is exacerbated by the poor state of knowledge in research into innovation processes (c.f. Winch, 1998). Harty (2008) points out the dearth of studies that investigate the processes of innovation implementation in construction. In a recent review of the state of the science in innovation, Anderson et al., (2014) observed a move away from process research which has led to a limited understanding of the processes of innovation. They call for more process research, to make the notion of process and interaction the point of departure. An innovation process study will help gain a deeper understanding of how and why innovation unfolds over time in construction and increase understanding of the processes and behaviours that are necessary for effective development and implementation of innovations. A process theory will not only provide an insight into the transformation of an idea but will also produce a model of innovation process for construction which can serve as a roadmap to managers of innovation, depicting paths that result in success or failure of an innovative idea.

2. Innovation defined

Various attempts have been made to define innovation. According to West and Farr (1990), innovation as a term has been used in many ways and the variance appears systematic with the level of analysis used, and is often very much varied and vague the more macro the approach becomes. Sexton and Lu (2012) suggests the need to adopt a view of innovation that is suited for particular contexts. Zaltman et al., (1973, p. 10) consider innovation as “any idea, practice or material artefact perceived to be new to the unit of adoption” whilst Van de Ven (1986, p. 604) emphasized the transactional nature of innovation and defined innovation as “the development and implementation of new ideas by people who over time engage in transactions with others within an institutional context”. In the construction management literature, Slaughter (1998) defines innovation as “the actual use of a nontrivial change and improvement in the process, product or system that is novel to the institution developing the change”. This paper adopts a more comprehensive definition of innovation proposed by the OSLO manual (OECD, 2005) that consider an innovation as “the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations"

3. The nature of construction innovation

Construction innovation can take a number of different forms regardless of the type of innovation involved. Tatum (1987) proffers four ways by which technological innovation occurs in construction: adoption of new approaches from external sources; modification and adaptation of existing technologies; incremental improvement of existing technologies; and the development of new technologies. The source of these ideas may be from research and development processes, leaders in the industry, leading suppliers and product manufacturers from other industries, competitors adopted or developed technologies or from experienced clients. Various typologies of innovation have been put forward. A popular typology is that of Slaughter (1998) who categorize construction innovation into incremental, modular, architectural, system and radical. Much of the innovations in construction according to Koskela and Vrijhoef (2001) fall into the incremental and modular categories of Slaughter's classification.

Construction innovation occurs at the sector, business and project levels (Abbott et al., 2007). Innovation on construction projects include process, product and organizational innovations which can be established innovations in the industry or custom developed for specific projects with opportunities to be diffused on future projects. Construction innovation is described as hidden on projects occurring within teams and often developmental through interaction between stakeholders on site. NESTA (2007) in its report on hidden innovations presents four categories of hidden innovations that include locally-developed, small-scale incremental innovations that take place 'under the radar'. At the business level innovation is much more about developing resources and capabilities: research and development (R&D) and organizational development. Whilst R&D focusses on the development of new materials or improvement on existing ones, organizational innovation involves the generation of new or enhancement of existing supply chain arrangements, strategies relating to human resource management, business processes and practices (Abbott et al., 2007; NESTA, 2007) or health and safety policy (Sexton & Barrett, 2003). Innovation at the sector level also takes two forms: through regulations and standards that prescribe new material attributes or behaviours which forces innovation, and the drive of innovation by client's that are dominant enough to drive innovation in the sector or rather for their specific needs (Abbott et al., 2007).

4. Theoretical framework

A number of models and frameworks have been proposed for the study of the process of innovation in organizations. Such models, often from product development perspective propose frameworks or models that are linear and generic (e.g. Zaltman et al., 1973). Some construction management researchers have also proposed similar generic models of the innovation process in construction organizations (e.g. Gann & Salter, 2000; Winch, 1998). Researchers in the Minnesota innovation study programme proposed a comprehensive but succinct framework for the study of the innovation process that doesn't only look at the process itself but concepts that feed into, drive or result from the innovation process. Van de Venn and Angle,(2000) rather summarize these concepts in the framework that: "from a managerial perspective, the process of innovation consists of motivating and coordinating people to develop and implement new ideas by engaging in transactions (or relationships) with others and making the adaptations needed to achieve desired outcomes within changing institutional and organizational contexts". The framework for their study of innovation process involves six concepts: ideas, people, transactions, process, context and outcomes. Changes in these concepts constitute an event which is mapped over the period of development and implementation of the innovation.

4.1 Innovation Ideas

Innovative ideas can be of different forms and from a myriad of sources. Ideas might be a recombination of old or existing ideas, something new that challenges the status quo or something new to the people involved (Van de Ven & Angle, 2000). Innovations are often a combination of emergent processes, adopted and adapted procedures often in use elsewhere and ideas that become refined over time through realistic organizational limitations (West, 2002). Therefore, the newness characteristics tell whether the innovation is new to the world or to a given context. Rogers (1983, p11) put forward that innovation involves products or services that are considered new to a social system with little emphasis on whether the newness of the idea is objectively assessed as by the time lapse since the first use of the product or service. Gopalakrishnan and Damanpour (1997) for instance consider newness as a function of the field's unit of analysis which goes to determine whether the innovation is new to an individual, group or team, an organization, industry or society in general. This degree of newness separates, or can be used as the basis to distinguish innovation generation from its adoption, and newness has often been considered as an empirical question for experts or executives of firms to address (Damanpour and Wischnevsky, 2006).

4.2 Individual engagement in innovation process

The role of individuals in the innovation process in organizations has been reiterated by researchers in the creativity and organizational behaviour literature. Early attempts to study the role of individuals in the innovation process in organizations focused on creativity, considered the first stage of the innovation process (e.g. Amabile, 1988). Winch (1998) made the point that operational personnel are the sources of ideas in many work environments, often captured through suggestion systems and quality circles. This can be through their own experiences and knowledge or through what can be referred to as practitioner research. Yuan and Woodman (2010) give examples of such behaviours to include the search for new technologies, exploring and suggesting new ways to achieve objectives, adoption of new and improved methods of working as well as the investigation and securing the needed resources to implement new ideas. Individual engagement in innovative behaviours has been described in relation to idea generation, idea promotion (championing or coalition building) and idea implementation (Holman et al., 2012).

4.3 Transactions

Transactions are necessary is examining how relationships develop in the management of innovation. Such transactions according to Van de Ven and Angle (2000) could be in relationships among peers (team-member exchange) or hierarchical relationships between superiors and their subordinates (leader-member exchange) regarding their engagement in the development of innovations. It could also be about proposals and commitments regarding the search and allocation of resources or any arrangement with parties to undertake tasks needed for the innovation development. Transactions are deemed to be a dynamic process that consists of three stages: negotiations, agreements and administration (Commons, 1950; cited in Van de Ven & Angle, 2000). How transactions go can be contingent on the novelty of the innovative idea. Much more novel and radical ideas require more trial and error with repeated or renewed cycles of negotiation, commitment and administration (Fernandez, 2001; Ring and Van de Ven, 2000). Transactions in construction could be with clients, consultants or other units or teams in the firm that play a role in the development and implementation of the innovation.

4.4 Context for innovation

Innovation has often been described as context specific. Context has been described by Andriopoulos and Lewis (2009) as a set of pressures and stimuli that shape the behaviour of individuals and groups. Van de Ven and Angle (2000) consider context as the setting or institutional environment within which an idea is developed and implemented through transactions among people. Thus, context can be described as the environment within which innovation occurs and can be within a team, project, firm, network, industry or even a nation. The structures, practices and procedures of an organization can be crucial to creating the necessary infrastructure for the successful development/adoption and implementation of innovations. Van de Ven and Angle (2000) suggest that for technological innovation such context variables include institutional norms, basic scientific knowledge, financing and human resources.

4.5 Innovation outcomes

The outcomes of innovation are realized after their development/adoption and implementation. Scholars have often drawn attention to the positive bias that anything innovation is good. Innovation is considered to be new to the unit of adoption and with the anticipation to reap benefits from its usage or the changes that it brings to the organization (West & Anderson, 1996). As Van de Ven and Angle (2000) point out innovation is often seen as good as a new idea must be useful; being possibly profitable or to solve problems and often ideas that are not successful characterized as mistakes. The process through which teams or organizations achieve innovation, however, results in either positive or negative consequences. Janssen et al., (2004) put forward both benefits (e.g. successful innovation, cohesion, effectiveness and efficiency) and downside (e.g. failure of the innovation, less cohesion, ineffectiveness and resistance to future innovations) to innovation in teams. Effectiveness judgements can also be made during the process of innovation development and implementation and can change during the process of implementation depending on the judgement of stakeholders or their perception of how well the innovation is meeting their expectations (Van de Ven & Angle, 2000). These changes result from changes in targets and expectations often coinciding with some unanticipated problems and setbacks or shifts in organizational priorities. Perceived in process judgement of innovation outcomes according to Van de Ven and Angle (2000) is a consequence of actions as well as a predictor of future actions but rather often incomplete explanations of actions.

4.6 The process of innovation in organizations

The innovation process is considered to be much more complex than the decision to adopt/develop and implement change. For instance, King and Anderson (2002) opine that a lot of activities are required before the decision to adopt is taken which can include fact finding, politics and manoeuvres, negotiations as well as formal and informal discussions. Process models can be deemed to belong to either the rational or behavioural schools of thought. The rational school is considered to be the most dominant view that underpins construction literature as far as innovation process is concerned (c.f. Barrett & Sexton, 2006). King and Anderson (2002) suggests that existing rational models are based on theoretical speculation, are normative, and give descriptions of the process as a sequence of stages. These models often prescribe linear and often predictable stages of innovation which Sexton and Barrett (2003) regard as depicting the innovation process as rigid, multistage and linear in nature. The stages, however, could be dependent on the nature of innovation, source and context within which the innovation is implemented. For instance, innovations that are adopted for implementation are often considered to be much simple and linear whilst innovations that are developed or originate from the implementing organization can follow much more complex, iterative, and non-sequential trajectories (Wolfe, 1994), consistent with the description of the innovation process by Quinn (1985) as a controlled chaos.

5. Proposed framework and research agenda

Despite the comprehensive nature of the concepts in the Minnesota innovation studies framework, it is generic and lacks a strong theoretical grounding and focus. To address this is to introduce a new adapted framework that is rooted in theories that will give the findings much more focus. Therefore, a framework that adapts the Minnesota innovation studies framework is proposed **(fig.1.)** which is rooted in the theories of ambidexterity and intellectual capital. In presenting an input-process-output model of ambidexterity, Simsek (2009) conceptualize exploration and exploitation as the components of the process with inputs that drive such processes existing at different levels of an organization. This input-process-output model can be adapted to investigate the process of explorative and exploitative innovations and their inputs at different levels of organizations that underlie the process of such explorative and or exploitative endeavours. Such inputs occurring at different levels of the firm can be intellectual capital: human capital, individual characteristics and individual engagement in the process; social capital and transactions between stakeholders; organizational capital that reflects the context within which the innovation occurs can be explored in terms of its facilitative ability or otherwise in explorative and exploitative innovative processes which are either adopted or generated. The output following Simsek's model would be the possible consequences of innovation processes at different levels which could at the individual, team, project or firm depending on whether the innovation is bottom up or top down. In the context of construction, the output of innovation could mainly be the consequences for the project as well as for the firm involved. Again the Minnesota framework is silent on the incentive or motivation as all innovations require that before they are initiated and is required before any innovation process commences.

5.1 Motivation or trigger for specific innovations

This is what Van de Ven (1991) describe as shocks that trigger innovation which can be opportunities for improvement, identified problems or competition from the environment. Individuals often go through the cognitive process to come up with novel solutions to problems or as opportunities for improvement (Holman et al., 2012) often with the identification of a problem that needs solving, a threat requiring urgent attention, an opportunity to improve current or existing conditions. Drucker (1985) identified sources of innovation opportunity to include: new knowledge, industrial changes as well as unexpected success or failure. Motivation or the trigger from sources both within and outside the organization sets the stage for concrete actions to pursue or undertake specific innovations regardless of the availability of the appropriate organizational climate (Van de Ven, 1991).

5.2 Explorative and exploitative innovative ideas

Part of the definition of an innovative idea is its characterization into different typologies and one such classification is whether the innovation idea constitutes an explorative or exploitative innovation (He & Wong, 2004; Jansen et al., 2006). Exploratory innovations offer new designs and create new markets requiring new knowledge (Benner & Tushman, 2003; Jansen et al., 2006). Exploitative innovations rather tend to improve and expand on existing knowledge and skills, brings improvement in efficiency and builds on existing structures and processes (Benner & Tushman, 2003). Whilst some researchers equate exploration and exploitation respectively to incremental and radical innovation, others have moved away from such classification for less technology intensive firms where there are less research and development activity (e.g. He and Wong, 2004) and firms undertake problem-solving activity using new knowledge, methods and techniques or refine and reuse existing knowledge, technologies and methods. Both forms of innovations entail knowledge combinations where one utilizes the existing and well-understood ways with the other leveraging knowledge that is varied and dispersed. Exploitative innovation demands efficiency and convergent thinking to be able to harness existing capabilities to improve products and services on a continual basis whilst explorative innovation involves efforts to generate novel recombination of knowledge, technologies and methods through search and experimentation (Andriopoulos & Lewis, 2009).

5.3 Human capital and individual role in innovation

The ability of an individual to actively be involved in the innovation process in organizations could be attributed to their innovation competency. Innovation competency according to Cerinsek and Dolinsek (2009) is to "act and react in an innovative manner in order to deal with different critical incidents, problems or tasks that demand innovative thinking and reactions, and which can occur in a certain context". This competency might also be underlain by factors as creative ability, education, training and experience which constitute human capital and is a source of knowledge and a resource for firms. Individuals association with the innovation unit according to Van de Ven and Angle (2000) is dependent on their skills, background, the frame of reference, experiences and activities that occupy their attention. Amabile (1988) suggests that the individual's creative behaviour is shaped by expertise, creative thinking skills and intrinsic task motivation. As Van de Venn and Angle caution, people as creators or facilitators of innovation must be balanced with people as inhibitors. This is against the backdrop of the fact that human beings have limited capacity in dealing with complexity and tend to adapt unconsciously to incremental changes often conforming to the group and organizational norms. This raises the question of how individuals can become invested in the development of new ideas given the tendency to focus on and protect existing practices (Van de Venn and Angle, 2000).

5.4 Social capital and transactions

Transactions and relationships might require internal and external social capital to be successful. Social capital is considered to be the network of interrelationships that aids knowledge exchange and integration within a firm. Adler and Kwon (2002) propose three dimensions of social capital: structural, cognitive and affective social capital. These complement each other in creating opportunity, motivation and ability to exchange knowledge. Social capital facilitates the exchange of knowledge, insights and mental models, improving the richness of exchange of information and iteration (Subramaniam & Youndt, 2005) which is relevant in transactions among parties involved in the innovation process. Social capital can be described as either cooperative or entrepreneurial. According to Kang et al., (2007) these two configurations of social capital can be identified especially in their alignment with exploration and exploitation. Cooperative social capital represents a social system that is tightly coupled with strong and dense networks of inter-connections. Entrepreneurial social capital, on the other hand, is characterized by weak redundant relational networks where members share a common component knowledge which is a reflection of their shared technical and professional knowledge (Kang and Snell, 2009). In effect cooperative social capital involves the existence of strong ties for the efficient sharing of knowledge whilst entrepreneurial social capital is about having access to a myriad of contacts from whom knowledge and expertise can be accessed when needed without necessarily having a close social relationship.

5.5 Organizational capital

Innovation in firms is developed in a context that can be reflected in the organizational capital. Organizational capital depicts the knowledge in processes, systems, structures as well as behaviour, norms, mental maps, core competencies and culture and is often context specific relating to the internal structure and organization of a firm. Organizational capital also consists of codified experiences and institutionalized knowledge that remain in the firm and used through databases, to preserve knowledge and to create routines, processes, structures and systems for continuous usage (Youndt et al., 2004). Organizational capital has been identified in two forms; mechanistic and organic (Kang & Snell, 2009). Whilst the mechanistic archetype involves detailing routines the organic type of organizational capital is about flexible or simple routines, priorities, vision and boundaries within which individuals and teams must work. This is more of a culture of conformity versus the encouragement of proactivity and creative thinking that can be associated with the empowerment or autonomy to be able to shape or challenge established norms (Kang & Snell, 2009). Thus, mechanistic archetype is where there are structures in place for coordination and control of activities and processes whilst the organic provides the flexibility to accommodate unexpected events and allow problem-solving through innovative thinking. The context can also relate to what Amabile (1988) refers to as an organization's motivation for innovation manifest in a number of ways either positive or negative to encourage or discourage innovative efforts in the organization.

5.6 Innovation generation and adoption processes

Damanpour and Wischnevsky (2006) argue that the process of innovation differ for innovation generation and innovation adoption and therefore how such innovations occur in organizations cannot be explained by the same theories of innovation. Generation is more of a creative process involving exploration of ideas, emergent and inherently characterized by variation and experimentation (March, 1991). Adoption, on the other hand, involves the adaptation of existing ideas and is more exploitative, planned and characterized by selection, refinement and implementation (Damanpour & Wischnevsky, 2006; March, 1991). Damanpour and Wischnevsky (2006) argue that such distinction between generation and adoption has often been overlooked by innovation researchers often referring to both as the innovation process. The requirement for success in innovation may, however, vary from one case to another or between innovations in different industries. Construction, for instance, provides a different context within which innovations are often adopted for implementation as compared to other high technology industries like manufacturing. This warrants a differentiation of innovation processes depending on whether innovations are adopted or generated for implementation and more so for contexts such as construction where the incidence of innovation might include both adoption and or generation.

5.7 Project and organizational outcomes

Outcomes of innovation in construction could be cost and time reduction in the execution of an operation, improvement of safety on site, reduction in environmental impact or improvement in the performance of the completed facility (Slaughter, 2000). Such effects ultimately impact the success of not only operations but projects and among a portfolio of projects affects the firm's performance and competitiveness. This reinforces the fact that innovation in construction not only benefits projects they are implemented on but also the parent organizations of the teams involved. Innovations developed on-site can help increase the capability of firms for innovation through learning and diffusion on future projects (Gann & Salter, 2000; Winch, 1998). Not all innovations are however successful, and failed innovations can have cost, time and quality implications. Failed innovations can as well impact relationships between parties or the image of the organization involved.

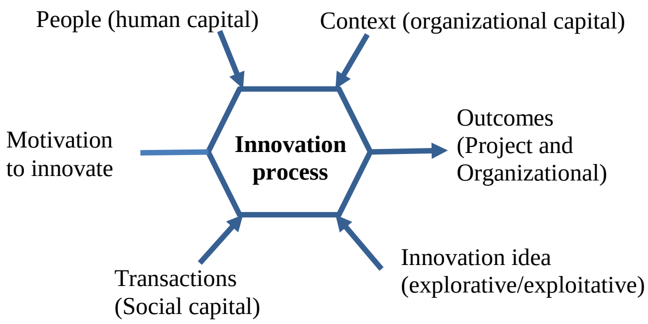

Figure 1: Conceptual framework for process of specific innovations

The forgoing discussion proposes a theory-driven framework and provides an agenda for exploring the process of innovations in the context of project-based firms where innovation is considered hidden and where the unique characteristics of the context and organizing have consequences for the innovation process. Therefore, it will be worth exploring or finding answers to the following questions: How are innovations adopted/developed and implemented by construction firms? How does the process of specific innovations differ depending on the innovation's attributes? What is the motivation for construction innovations and what roles do individual stakeholders play in the process? How does intellectual capital facilitate the process of innovation development/adoption and implementation by construction firms? And what are the consequences of the innovation processes for projects and organizations involved?

The above forms part of an ongoing research aimed at creating a process theory of innovation in construction. Data is to be collected through case studies using mixed methods: retrospective interviews, ethnographic interviews and observation. The critical incident technique is to be adopted in the interviews to focus on critical or significant moments and events that define the innovation process. Case study firms and innovations are to be carefully selected to consist of firms of different sizes as well as innovations of varied attributes. Cluster analysis could be used to distinguish innovation processes by type or attributes in an attempt at creating a differentiation theory by identifying patterns within and across clusters.

6. Conclusion

The framework presented here departs from the Minnesota innovation studies framework and existing process studies by including intellectual capital and ambidexterity theory. The nature of construction being a project based industry suggests that the nature of innovative ideas, multifunctional personnel and contexts differ from that of permanent organizations that have been the contexts for many innovation process studies. A study of innovation process as proposed in the advanced framework will be one of the first few attempts to provide an innovation process theory for construction and project based firms based on empirical studies of specific innovations. This proposed study will also help create a differentiation theory on innovation process not only for explorative or exploitative innovations but also whether innovations are bottom up or top down, product or process etc. Finally, the paper presents how intellectual capital can facilitate innovation through individuals (human capital), social capital in transactions and organizational capital in providing the appropriate context for innovation. Such a study will help point out the criticality of human, social and organizational capital in facilitating the innovation process of specific innovations adopted/developed and implemented by construction firms. It will also potentially provide a model for innovation process in construction that can help managers better manage intellectual capital to enhance the innovation process and its outcomes.

Design and Prototyping of a Curtain Wall System With Wooden Load-bearing Structure and Glass Infill Panels

Massimo Rossetti[1], Michele Menegazzo[1], Stefano Spina[2] and Gloria Pezzutto[2]

Università Iuav di Venezia
Email: rossetti@iuav.it

Abstract

The sector of architectural envelope is at the moment one of the most developed, both in terms of technological innovation and design experimentation. The whole construction industry knows that the curtain wall performances are essential to reduce the impact of buildings in the environment, in terms of greenhouse gases emissions and energy consumption. At the same time, a positive trend for the buildings with wooden load-bearing structure has developed and it is proved by a growing number of projects in geographic areas where historically no-one used this material. The wood is highly appreciated in the field of construction industry because of its good mechanical resistance, its good thermal insulation and sound-proof, the ease it can be worked, the tactile heat that transmits and the message of environmental eco-friendly improvements it can be associated with. After a meticulous observation of these trends, the Università Iuav di Venezia has decided to develop a specific research project: it has prefigured that a work in synergy between the two sectors can offer a fertile ground to develop technical and planning know-how. The aim is to develop prototypes of innovative curtain walls with wooden load-bearing structure and glass infill panels. A market survey has shown that wood curtain walls are almost absent, that's the reason why it has been chosen to analyse and develop this kind of product with the partnership of Simco Tecnocovering (nowadays Simeon S.r.l.), an Italian company specialized in aluminium curtain wall systems. It has been decided to set aluminium systems with wooden envelopes and a mixture of aluminium and wooden structures made by the most important competitors against a façade system only made of wood. The paper presents the final results of the research, underlining the problems observed and the solutions that have been found.

Keywords: Architectural envelopes, curtain wall, wooden structure, glass infills, sustainability

1. Introduction

The development of a curtain wall system with wooden load-bearing structure and glass infill panels was the goal of this experience. The project included also activities evaluation, as well as the technical and technological aspects, about the "patentability" of the system.

A curtain wall (according to EN 13830:2015 "Curtain walling – Product standard") consists of *"a part of the building envelope made of a framework usually consisting of horizontal and vertical profiles, connected together and anchored to the supporting structure of the building, and containing fixed and/or openable infills, which provides all the required functions of an internal or external wall or part thereof, but does not contribute to the load bearing or the stability of the structure of the building. Curtain walling is designed as a self-supporting construction which transmits dead-loads, imposed loads, environmental load (wind, snow, etc.) and seismic load to the main building structure"*, and it is normally made with an aluminium structure.

Despite the excellent technical and performance characteristics of the aluminium, using wood as a structural material brings undoubted positive effects in terms of environment preservation, in addition to satisfying a market sector that requires aesthetic standards related to the use of natural materials. Instead of aluminium, in fact, the use of wood would mean fewer problems of thermal bridge, the use of a material with a lower embodied energy (the amount of energy required to produce a unit of material starting from the raw material), in addition the obvious advantages of static (it is lighter). In a territory, also, as we have been seen, particularly receptive for the development and production of envelope systems.

Goal of the project was therefore the development of a patent system of bloc curtain wall made in wood/glass, based on the know-how of the producer in a first and recent application "pilot" of this system on a building in France.

2. Description of the research project

The research project was born from the participation of Veneto Region, during the period 2007-2013, to the European Social Fund program that is part of the European Community strategic guidelines focused to strength economic and social cohesion of the European Union by reducing economic, social and territorial disparities among Member States and the regions of the Union. This was achieved through the European "Regional Competitiveness and Employment Objective" which established the strategy, the priorities and objectives of the European Social Fund (ESF) in every specific regional area. In this context, in 2013 the Veneto Region has supported and funded a program called "ESF – Axis Human Capital – Research Grants" for the presentation of postgraduate research projects that include cooperation between a university and a company based in Veneto Region (called "operating partner"), with the target to train and employee young researchers. In this context, 127 research grants – 49 assigned to the Università Iuav di Venezia – started, with a total funding of more than 6 million euro.

The Università Iuav di Venezia in collaboration with Simco Tecnovering S.r.l. (company specialized in curtain wall systems) as operating partners developed a research project. The role played by Simco Tecnovering was a technical support during the design phase of a new curtain wall system in wood and glass. The level of involvement of the operating partner was comprehensive, because it took place during most of the period of research project. The operating partner was the main promoter of the research project, having identified the market potential and, thanks to the experience developed in this industrial sector, having the specific technical skills to develop the prototype. The position of the operating partner in the regional, national and international market also allows to directly focus in the dissemination of results.

The research project takes place in the building envelope and curtain wall area, particularly in wooden doors and windows sector, of great importance both nationally and regionally. According to the available data at the time of the research project, the Italian market of windows and architectural envelope was about 5 billion Euros worth (2011, Studies and Research Service of the Chamber of Commerce of Verona, data InfoCamere), where the curtain walls sub-sector amounted to nearly 500 million euro (2012, Uncsaal/ISTAT data). Particularly, concerning wooden window frames, the market reached the billion and a half total turnover (2011 data, Studies and Research Service of the Chamber of Commerce of Verona, data InfoCamere).

The Veneto Region is particularly important concerning energy saving measures: almost all – about 95% – of works carried out on buildings in 2011 was the replacement of windows. Concerning the replacement of windows, 10.2% of the total amount of work in Italy took place in Veneto, ranked fourth after Lombardia, Piemonte and Emilia Romagna. Veneto is in fourth position in Italy also as total surface installed, with over 250,000 square meters. (2011 data, Enea Annual Report – Tax deductions of 55% for the energy upgrading of existing buildings).

All across Europe the awareness that the wood can become a key material for the construction industry, not only for small private buildings but also for large structures, is constantly growing. In Berlin new residential houses will totally made of wood; in Sweden skyscrapers are designed also in wood, while in France the government announced that the construction will be stimulated by new tall buildings with wooden frame, together with a policy development of forests supported by the Ministry of Agriculture.

Architectural envelope prefabrication allows to reduce waste, to control the quality of the product, to test its real performance, to inspect the equipment on site and to speed up the assembly stages. Systems of mixed wood-aluminium façade are present on the market, but no system is completely made of wood; moreover, they are usable for several types of buildings (residential, office, school, etc.). This was the main focus of the research, being also a development opportunity for the Veneto Region.

3. Organization and methodology

The research, which took place from March 2014 to March 2015, was divided into four phases. The first phase was focused on the collection and analysis of information related to the research project, with particular reference to the technical aspects of the building envelope and windows. It covered a period of about two months and was carried out mainly in the Università Iuav di Venezia. The first phase included five additional sub-phases:

1. The analysis of classification systems for building envelopes according to UNI 8290-1: 1981 + A122: 1983: *Edilizia residenziale. Sistema tecnologico. Classificazione e terminologia*;
2. The analysis of the main systems of building envelopes, in particular those related to the UNI EN 13830: 2005 *Curtain walling. Product standard* (still current at the time of the research project, now substituted by EN 13830:2015 *Curtain walling. Product standard*);
3. The analysis of the physical/technical (thermal, light, sound, fire safety, etc.) factors involved and of the performance levels of the main types of architectural envelopes currently available;
4. The analysis of the main types of wood species currently used for architectural envelopes;
5. The analysis of the physical/technical (thermal, light, sound, fire safety, etc.) factors involved and of the performance levels of the main types of the glazing systems currently available on the market.

The first phase allowed to get a comprehensive state-of-the-art of curtain wall and architectural envelopes sector, updated to the most recent technical solutions. This phase prepared a solid background for the research, before starting the true design process.

The second phase focused the methodology of design and production of curtain walls. It covered a period of about three months and was carried out between the Università Iuav di Venezia and the corporate headquarters. It included four additional sub-phases:

1. The analysis the dynamics of the curtain wall industrial sector and of the operating partner organization, of its technical/economic departments and business function, of its production facilities, of the commercial network, of systems and products already on the market;
2. The analysis of the UNI norms concerning curtain walls systems;
3. The analysis of laboratory tests and tests aimed to design and produce a curtain wall;
4. The collection of information about similar existing wooden structure systems, with glazed infill panels, and the analysis of their characteristic.

The second phase allowed to better understand the operational partner and its industrial organization; moreover, the second phase allowed to collect information about similar products already on the market, in order to focus the design process in a better way.

The third phase included the design and prototyping of the curtain wall system in wood/glass. It covered a period of about six months and was carried out between the Università Iuav di Venezia and the corporate headquarters. It included two further sub-phases:

1. Study of a curtain wall system with wooden frame and glazed infill panels;
2. Mock-up of the system itself.

The third phase was the true design phase, when all the information collected during the previous phases were put together in order to prepare a mock-up to be later verified in its formal and technical aspects.

The fourth and final phase, which lasts about a month, took place between the Università Iuav di Venezia and the corporate headquarters, included the making of a video of the whole process and the preparation of a book with the technical/performance characteristics of the system.

4. Phases of analysis, design and prototyping

Based on the information gathered during the analysis phase, we found that in the market there aren't systems of wooden facade entirely of wood, but there are always metal elements especially for the connection between the carrier and plugging.

We considered the multiple needs related to marketing, to engineering, production, installation and maintenance of the same during the design phase of the system. For this reason we developed a process of continual review, but at the same time the result is a product more in line with actual needs of future customers.

The system is a curtain wall, female-female typology: this solution allows to optimize the number of profiles, to facilitates the industrialized production of the modules and to do a faster assembly of the element. It is available in two versions:

- With external caps: the fixing of the glass takes place with a mechanical system;
- Full glass structural version: the fixing of the glass takes place using particular adhesives.

System with external caps
A great potential of the system is linked to the possibility to product particular forms, customized shape for the structure of the façade (mullion and transom) and the outer cover. Contrary to the extruded aluminium, which features production must maintain a constant shape, wood is malleable and can be modelled.

Full glass structural version
This version of the system is studied to obtain a full-glass aspect. The bonding of the glass to the structure was made with a particular adhesive. The supplier of the adhesive tested this fixing system and the process of certification of the product is just started. This product is applied in

wooden support after that it is cleaned and treated with the primer. The tightness is immediate so that the block can be immediately moved with glass suckers. The maximum tightness is achieved after 60 hours after the application. This system minimizes the strips that we should normally have with the use of structural silicone, speeds up the production process and guarantees high performance.

One of the crucial problems to be solved was the system of engagement and disengagement of the elements of connection between the main frame and the glass panel. We thought about maintenance methodology.

In the course of the useful life of the building in fact it is possible that some glasses break due to accident, breakage due to nickel sulphide in tempered glass (also with HST) and the replacement of these collisions is often not a simple operation. In Francophone countries, the main market for the company, if the structural glazed infill breaks, it can not be replaced directly on the jobsite, but, as opposed, it is necessary to remove the sub-frame and proceed with the replacement in the factory or in a protected and dedicated area. These solutions are already been broadly applied for aluminium facades or for mullions and transoms curtain wall, but there aren't many application in wooden façade. The main difficulties concerning the needs to ensure adequate mechanical strength, to contain the width of the profile and to minimize the use of metallic materials, both for thermal reasons, both for evaluations on the life cycle of the product. We overcome these aspects proposing a punctual anchor that allows the replacement of vision modules from the inside and the replacement of shadow box part from the outside. The method of replacement is safe and easy: we can also keep some replacement element already glazed in the building, ready for use. During the study of the system we considered various types of openings (bottom hung, top hung, pantograph) and we studied accessories of hardware ad hoc, due to the size and of the loads involved. We can integrate the bloc with different types of internal and external solar screening: screening curtains, brisesoleil, blinds, architectural louvers, mobile systems. Also claddings can be different: glass (monolithic, double glazing, triple glazing) or opaque (enamelled glass, wood, plastic or metal sheet). The basic system is in laminated wood. We can also use microlamellar to increase performance static. Wood species can be chosen by the architect. You can also choose the wood finish. You can use the natural wood (accepting the uncontrolled maturation and reaction to weather), treated with paint (that make it stable over time but it will reduce the natural variability) or earlier aged (the change is more controlled and the material is more stable).

Figure 1: the two prototypes of the wood/glass façade.

5. Discussion

One of the most important point of discussion is the introduction of a wooden frame as substitute of aluminium as structural material for curtain wall. Since aluminium is largely considered as the main structural material in curtain wall industry, one of the targets in the following steps will probably be spreading the results to convince potential architects, clients and users of the possible applications of this façade system. Actually, considering the characteristics of the system, we can state that:

- Static performance are satisfactory: the system is dimensioned to respond to a wind pressure of 1250Pa (a pressure which is normally used for mid-rise towers, about 14 floors). We can review this performance according to different needs by changing the size of the profile or type of wood;
- The thermal and acoustic performance are very good being the wood a naturally insulating material;
- The embodied energy is less than traditional aluminium systems;
- It's possible to disposal the envelope after its phase of life. It is disposable and recyclable since the system is composed by a single material or different materials easily divided into the various elements and it will not become hardly disposed.

The following picture can, at a glance, summarise and compare the different characteristics of an aluminium and a wooden frame curtain wall.

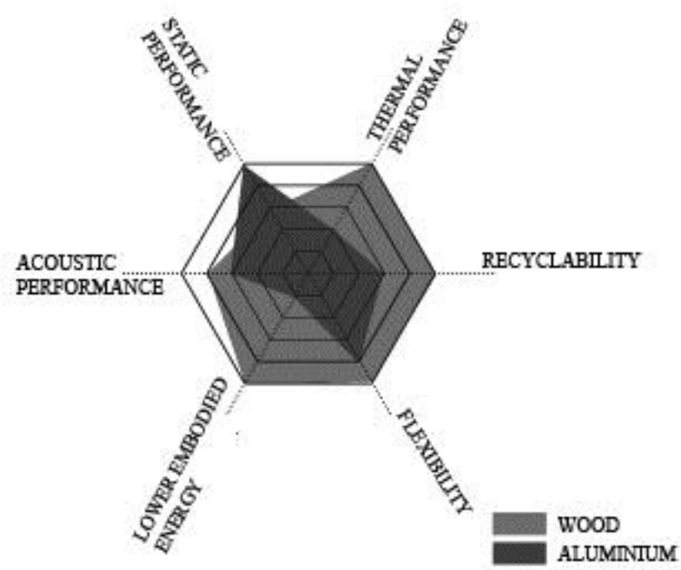

Figure 2: comparison between aluminium and wooden frame curtain wall.

Wooden frame can represent a valid alternative to aluminium façades, especially considering its lower embodied energy and the thermal performances. We can also consider wood like a sustainable material if we develop correct reforestation policies with the aim of increasing our forest resources. In this way we can obtain more natural resources, a reduction of emission, a increment of the use of recyclable materials.

Moreover, since one the most important targets of the Veneto Region "ESF – Axis Human Capital – Research Grants" program was to supported the occupation, the introduction into the construction building materials and products market of a brand new façade system, potentially usable in several different building typologies, can have the impact to push other companies to develop similar systems, with the consequent impact of new possible work assumptions. In fact, the design, prototyping, engineering, production and installation of a new façade system by a specialist company, able to carry out research applied, is in fact one of the motors which allows, subsequently, other operators to propose their own solution, triggering a virtuous circle that can bring, as well as a new market and a benefit in terms of employment.

6. Conclusions

The industrial nature of the Veneto region and of the whole Italy is particular fruitful for closures and the window frame sector. This research that aimed at the development of an innovative system of closure with wooden frame and glass curtain, virtually absent from the market certainly brought advantages to operating partner, but also to their suppliers and to the business world linked in similar activities. The design of a new system involved the use of resources and an initial investment that will to return in economic, commercial, image, etc. positive effects.

Architectural envelope, and especially façades and curtain wall, that represent one of the most important sectors in construction industry, both from formal and technical point of view, are highly important in the energy balance of a building, since thermal performances of the envelope deeply influence the internal comfort and energy consumptions. Also, the use of wood as structural material can be a valid alternative to more common aluminium structures, that can be used various building typologies (residential, directional, commercial, etc.). Moreover, this type of curtain wall can be largely used both in new and refurbishment projects.

Considering the objectives of the research and the prototype characteristics, the final results can be considered largely satisfying. The prototype represents a good example of a new system that is quite absent from the façade market and has some peculiarities that can satisfy designers' and users' needs.

Abstract

In construction, the progress of the project is driven primarily by the construction project programme or schedule and the Construction Project Manager (CPM). The project programme sets out the bases for monitoring and controlling the project by the CPM. Many construction projects in the public sector are subject to late completion, cost overruns and poor quality arguably as a result of inadequate programme management. During the construction phase of projects, there are many opportunities for the CPM to implement lean tools and techniques that will have a positive impact on the project from a programming perspective. This study investigated the impacts of implementing lean project management (LPM) tools and techniques during the construction phase of public sector projects on the successful delivery of the programme. A sample of 234 registered CPM's were surveyed to determine whether they were aware of LPM and identify how often they used LPM tools and techniques under the nine project management areas of expertise to achieve the successful delivery of the programme. Seventy two responded to the survey questionnaire. It was found that CPM's are aware of LPM and are utilising these principles under the nine project management areas as an initiative towards improving the delivery of the programme during the construction phase of public sector projects. It is evident that there is consensus between LPM principles used often to always under the nine project management areas. The data did however, identify that not all of the LPM principles are equally implemented under each area of expertise. This study was limited to professionally registered CPM's involved in the public sector based within the KwaZulu-Natal province of South Africa.

Keywords: Construction Phase, Construction Project Managers, Lean Project Management, Project Programme, Public Sector.

1. Introduction

A key stimulator of economic growth is the construction industry (National Treasury, 2015). This stimulation is accomplished by increasing the productive capacity of the economy through the provision of infrastructure to both private and public sectors. One of the fundamental challenges of the South African government is service delivery in the construction sector. Some of these challenges are highlighted by the South African Government New Agency Report (2015) as, delays and disruptions during construction, poor site management, time and cost variations, skills and competence issues, lack of quality improvement processes and lack of worker participation.

There are numerous performance indicators regarding service delivery in the construction industry (Chan and Ada, 2004). Time is one of the most important factors taken into consideration regarding the successful delivery of construction projects in the industry. Time is monitored and measured against the construction programme on public sector construction projects during the construction phase. The construction programme as defined by the Project Management Book of Knowledge (PMBOK) (2004) includes the processes required to accomplish timely completion of the project.

Construction usually involves the interpretation of the Client's brief into a design and then translation into reality. This translation requires a design or consultant team selected by the Client/ Employer. Construction Project Management is defined by the South African Council for the Project and Construction Management Profession (SACPCMP) in terms of the Project and Construction Management Professions Act (2000) as the management of projects within the built environment from conception to completion, including the management of related professional services. The CPM is the single point of responsibility in this regard. More specifically this study makes reference to CPM's appointed by the Public Sector to manage and deliver successful construction programmes during the construction phase of projects in the industry.

Truman and King (2013) note that the successful delivery of construction projects in the public sector are hindered by poor programme management. These are failure to adequately programme the work and properly execute the programme, failure to provide adequate qualified human resources to manage the programme, failure to develop an efficient programme and to effectively maintain the programme throughout the project execution and failure to control cost changes that impact the programme throughout the execution of the project.

Lean project management as defined by Pfeiffer and Weiβ (1994) is a system for organising and managing all aspects of a project function by creating principles, practices and tools in order to develop goods and services with higher quality and fewer defects. The general outcome is to do this by using less effort, space, capital and time. In construction, lean project management is delivering more value with less waste in a project context.

A study conducted by Rust and Koen (2011) revealed that the South African construction industry is renowned for low levels of innovation towards stimulating technological solutions to provide and maintain future growth of the industry. As a result, the research conducted in this study aims to identify and highlight lean project management and its implementation as an innovative initiative towards the successful delivery of the project programme. The study aims to achieve the following objectives, to determine whether CPM's are aware of LPM and to identify how often CPM's use LPM tools and techniques under the nine project management areas of expertise towards the successful delivery of the programme.

2. Literature Review

2.1 Lean Project Management

Lean thinking is a philosophy based on the concepts of lean production (Koskela, 1992; Koskela, 2000). Alternatively, the first consideration of the ideas of lean production for use within construction is attributed to Koskela (1992) (Garnett, *et al.*, 1998; Mossman, 2009). Lean construction is a different project management approach because it has a clear set of objectives for the delivery process, is aimed at maximising performance for the customer at the project level, designs concurrently product and process, and applies production control throughout the life of the product from design to delivery (Howell, 1999).

Lean project management builds on the understanding that no other project has been or will be exactly the same as the one you are currently working or preparing to work on. It takes a practical approach with simple steps to demonstrate how to complete projects in half the time, all the time. LPM assists project managers taking on more projects, wanting to complete them faster with less team stress (Leach, 2006). LPM is the inclusive adoption of other lean concepts such as lean construction, lean manufacturing and lean thinking into the project management context. LPM has numerous ideas in common with other lean concepts. However, the fundamental principle of LPM is delivering more value with less waste in the project context. LPM has many techniques for implementation to projects and one of the main methods is standardisation (Leach, 2006).

2.2 The Public Sector

One of the fundamental challenges of the South African government is service delivery in the construction sector. In recent report presented by Public Enterprises Minister in 2015, it was highlighted that although the government considers the public sector to be part of the country's economic fibre, the sector is confronted with major delivery challenges. Some of these challenges faced during the course of executing construction projects include: delays and disruptions, poor site management, time and cost variations, skills and competence issues, lack of quality improvement processes and a lack of worker participation. As a result, there is no doubt that substantial improvements in quality and efficiency are needed and are possible (South African Government News Agency, 2015).

Project risks further highlighted by the Price Waterhouse Coopers (PWC) report: SA Construction (2014) includes project execution, noting the challenges as: the competitive nature of the market as well as skill shortages which places pressure on companies to deliver projects. This then poses a risk to companies' ability to start projects efficiently, manage changes in projects, manage limited resources and complete and handover projects. The report further identifies the proposed actions required by the industry as: Implementation and monitoring of project management procedures and policies over the life cycle of a project; and assignment of accountability is imperative in mitigating the risk posed to project execution. This reinforced the initiative proposed by the research regarding the implementation of LPM during the construction phase of public sector projects as an initiative towards the successful delivery of the programme.

2.3 The CPM Profession

Construction project management is project management applicable to the construction industry which is aimed at meeting the client's requirements in order to produce a functional, feasible and financially viable project. The CPM's roles involve overall planning, co-ordination and control of a construction project from initiation to completion (Burke, 2003). More specifically this research makes reference to CPM's appointed by the Public Sector to manage and deliver successful construction programmes during the construction phase of projects in the industry. In construction, the selection of the CPM is a key appointment which can influence the success or failure of the project. As the single point of responsibility, it is the CPM who integrates and co-ordinates all the contributions and guides them to successfully complete the project (Burke, 2003).

2.4 The Construction Phase and Project Programme

The progress and success rate of the project is driven primarily by the programme and the CPM. The project programme sets out the grounding upon which the project is monitored and controlled by the CPM (Truman and King, 2013). Determining what work must be done, what resources including human resources are to be used, together with the identification of equipment, facilities and funds needed for projects reinforces the need and importance of having a sound project programme to manage these deliverables. The aim of the programme is to provide a plan that is well thought out and realistic which can be achieved.

Many construction projects in the public sector are subject to late completion, cost overruns and poor quality as a result of inadequate/poor programme management (Truman and King, 2013). During the construction phase of projects, there are many opportunities for the CPM to implement lean tools and techniques that will have a positive impact on the project from a programming perspective. Watt (2014) further notes that during the construction or implementation phase, the project plan is put into motion and the work of the project is performed. Progress is continuously monitored and appropriate adjustments are made and recorded as variances from the original plan. The programme is updated and communicated on a regular basis. In any project, a project manager spends most of the time in this phase.

2.5 The Relationship between LPM, the Public Sector, the CPM Profession, the Construction Phase and the Project Programme

Evidence of the use of lean thinking has shown that there are many benefits to be made from applying lean principles to construction. These benefits claimed include, improved productivity, increased reliability, improved quality, more client satisfaction, increased predictability, shortened schedules, less waste, reduced cost, enhanced buildability improvements to design and improved safety (Lehman & Reister, 2004; Mossman, 2009).

Government, industry and clients are all seeking to bring about a change in the construction industry to improve quality, competitiveness and profitability, and to increase value to clients. Where the emphasis has traditionally been on the need to manage the interface between the project and the client's organisation, it is now shifting towards the need to manage the flow of activities through the whole life cycle of the project, concentrating on those activities that actually add value (Matheu, 2005). The South African construction industry plays a major role in contributing towards the gross domestic product (GDP), highlighting its major role of adding towards the growth and development of the country. It has been identified that the construction management profession in the industry is one of the key roles and is the single point of contact between other consultant professionals on a project and the client. As a result, the success of the project ultimately rides on the unique management skills of the CPM.

The successful completion of construction projects are achieved when they are completed within budgeted cost, specified quality, stipulated time and delivered safely. One of the key tools identified in order to aid CPM's towards achieving this goal is the project programme. The application of sound project management principles on a project is not only the means to the projects ends, but aids in guiding and managing the project towards its successful completion while meeting the client's needs within the defined budget (Truman and King, 2013). This highlights the ability of CPM's to provide the public sector with the unique management skills they require such as LPM to assist in improving the delivery of the project programme. One of the key management areas highlighted that can be implemented by CPM's is LPM. CPM's need to implement LPM tools and techniques during the construction phase of public sector projects as an initiative towards improving the delivery of the project programme.

3. Research Methodology

In order to achieve these research aims, the research approaches adopted involved, conducting a comprehensive literature review which investigated the concepts of LPM, the public sector, the CPM profession, the construction phase and the project programme and the relationship between these areas of concern.

The study involved targeting all CPM's professionally registered with the SACPCMP in the province of KwaZulu-Natal (KZN). These registered CPM's were identified from the Professions and Projects Register (2015). This register lists 234 registered CPM's in KZN. Out of the 234 registered CPM's, 72 responded to the survey questionnaire. This represents a 31 per cent response rate.

The sample was surveyed to determine whether they were aware of LPM and to identify how often they used LPM tools and techniques under the nine project management areas of expertise to achieve the successful delivery of the programme. The data was analysed using SPSS version

23. Finally, conclusions were drawn from the research findings and recommendations for implementation are presented.

4. Findings and Discussion

CPM's were presented with the fifteen principles underpinning LPM and asked on a scale of 1 to 5, where 1 = never and 5 = always, to confirm how often they used these principles under the nine project management areas of expertise during the construction phase of public sector projects towards improving the management and delivery of the programme. The CPM's responses were ranked according to the mean scores presented in Table 1.

Table 1: LPM comparison with the Nine Project Management Areas of Expertise

Lean Principles and Techniques	Mean and Rank	Nine Project Management Areas of Expertise								
		Cost Management	Communication Management	Integration Management	Procurement Management	Human Resource Management	Risk Management	Scope Management	Time Management	Quality Management

	Rank	**7**	**2**	**5**	**9**	**1**	**8**	**4**	**6**	**3**
		(13)	**(3)**	**(10)**	**(13)**	**(2)**	**(14)**	**(8)**	**(11)**	**(4)**

(Note: Ranking in brackets refers to the LPM principles as used within each project management area).

Table 1 presented the means of responses to the frequency of the use of 15 LPM principles in each of the nine project management areas of expertise, highlighting where each principle was most frequently used. The following was noted regarding the principles critical to the successful delivery of the programme:

- Improving planning and communication was most often to always used under cost management, suggesting that planning and communication important towards ensuring the cost management is adhered to;

- Eliminating waste and errors was used often to always under scope management, indicating that it was important for CPM's not to deviate from the scope, as the primary objective towards completing the programme is to achieve the planned scope;

- Improving work planning and forward scheduling was used often to always under quality (1^{st}) and human resource (2^{nd}) management. This suggests that competent human resource selection including the quality of the works being executed was key towards ensuring that planning and scheduling is implemented efficiently;

- CPM's highlighted that eliminating activities that do not add value were most often to always used under cost management, indicating that by not deviating from the scope and adhering to the approved budget the primary objective of completing the programme timeously can be achieved;

- CPM's felt that implementing critical path analysis and programme management was used most often to always under Time (1st), scope (2nd) management, suggesting that completing the project on time and as per the approved scope was important to the successful delivery of the programme;

- Reduce lead time was used often to always under procurement management, suggesting that the procurement and delivery of materials in relation to the programmed deliverables were key towards the successful completion of the programme;

- Maximising workflow, minimising the performance variation rather than focusing on speed only, was used often to always under time management, indicating that completing as many work activities as possible, the right way, the first time around timeously was important towards achieving the target milestones governed by the programmed;

- Risk management techniques was ranked 1st under both risk and procurement management suggesting that CPM's find procurement a critical area that has to be managed towards ensuring that the procurement and delivery of materials coincide with the milestones highlighted in the programme;

- Implementing continuous improvement from one project to another was used often to always under human resource management (1st) suggesting that CPM's see the need to ensure that implementing continuous improvement from one project to another is carried out through human resource team on the project.

In comparison, Table 1 then presented the means of responses to the frequency of use of the nine project management areas of expertise in each of the 15 LPM principles highlighting were each area of expertise was most frequently used. The following was noted:

1. Cost management was used often to always under improving planning and communication, suggesting that improper planning and communication will have a negative impact on cost management for the project.

2. Communication management was used often to always under improving planning and communication suggesting that there is consensus with improving communication under communication management as highlighted by CPM's.

3. Integration management ranked 1st under benching marking techniques including the use of key performance indicators, highlighting that CPM's are tracking their performance by integrating benchmarking techniques and key performance indicators during the construction phase of the project.

4. Procurement management was used often to always under reduce lead time, suggesting that reducing the lead time under procurement management plays a vital role towards ensuring that delays in the programme are avoided as long lead items must be ordered timeously so that they are delivered and installed in alignment with the programme.

5. Human resource management ranked 1st under improving work planning and forward scheduling, indicating that CPM's prioritise improving the team's work planning and forward scheduling so that any anticipated delays or hold points can be identified prior towards eliminating possible delays so that the programme is delivered on time.

6. Risk management ranked 1st under risk management techniques highlighting that there is consensus between the application of the principle under the respective area of expertise.

7. Scope management was used often to always under direct intervention to drive immediate and apparent change, suggesting that CPM's ensure any changes to the scope that may impact the programme is driven immediately towards understanding the nature of the change, its impact on the programme and then determining the way forward.

8. Time management ranked 1st under implementing critical path analysis and programme management and maximising work flow, minimising the performance variation rather than focusing on speed only. This suggests CPM's ensure the management of the programme including the execution of the critical path is monitored closely during the delivery of the programme so that the project is delivered on time. In addition, it is also indicative that CPM's focus on maximising the workflow towards ensuring more work is executed and completed rather than increasing speed and minimising performance. As a result, progress of the works is capitalised on towards ensuring the successful and timeous delivery of the programme.

9. Quality management was used often to always under improving work planning and forward scheduling including risk management. This indicates that detailed planning of the programme including execution of same was seen as critical by CPM's towards ensuring that risks are mitigated and controlled so that quality is not compromised by abortive work being redone due to poor quality workmanship. This ensures that the programme is delivered on time but at a quality level that is acceptable and satisfactory.

The mean scores and rankings presented in Table 1 bring to light that CPM's are aware of LPM and are utilising these principles under the nine project management areas as an initiative towards improving the delivery of the programme during the construction phase of public sector projects. It is evident that there is consensus between LPM principles used often to always under the nine project management areas. The data did however, identify that not all of the LPM principles are equally implemented under each area of expertise.

5. Conclusions and Recommendations

Having reviewed the concepts of LPM, the public sector, the CPM profession, the construction phase and project programme including the relationship between these areas of concern and taking into consideration the results of the survey, this study comes to the following conclusions: It is evident that CPM's were implementing most of the LPM principles under the nine project management areas of expertise as an initiative towards improving the delivery of the programme during the construction phase of public sector projects. While other principles were only used seldom to sometimes, suggesting that there is room for improvement regarding the equal implementation of all principles under the nine project management areas. It was therefore concluded that CPM's are aware of LPM and are using these principles and techniques during construction projects towards improving the delivery of the project programme.

As a key role player on construction projects, CPMs were identified to be in an opportune position to drive the implementation of LPM on public sector projects. CPM's may consider partnering with the public sector to eliminate/ minimise challenges with implementing LPM principles under the nine project management areas during the construction phase towards improving the management and delivery of the programme. This could be facilitated through regular workshops and programming meetings being held with the public sector and CPM's during the projects life cycle, whereby the problems/ drawbacks are identified and listed, so that control measures are put in place such as risk management plans in order to monitor and avoid identified problems/ drawbacks including dealing with them immediately as they occur.

It was also found that CPM's were using LPM on an ad-hoc basis. LPM was being implemented where CPM's felt it needed to be applied and not as a requirement under all areas of expertise. Hence, it is suggested that the public sector promotes the implementation of LPM though the development of a policy for LPM implementation on their construction projects which will make room for LPM to be applied in a structured manner throughout the construction phase of public sector projects.

Abstract

This paper proposes a method named "3 Step Site Layout Planning" in order to define construction site organization. The designer is supposed to go, one after another, through three activities, that are: construction sequencing definition; transportation system choice; and site layout definition. The method is the nowadays version of an attempt of the authors to propose a useful tool to help construction managers to design their sites. A first approach was proposed, some years ago, based on the literature about the theme. After several uses in real construction cases, it was improved until the present status that is considered to fill manager needs. This method was used, by the authors, for as much as 50 real construction projects. In order to better explain the commented 3 steps, this paper describes one example of each step.

Keywords: Site layout, construction planning, construction design.

1. Introduction

Any industrial production description demands three types of design that are related to: the product being produced; the adopted process; and the factory that hold all the activities.

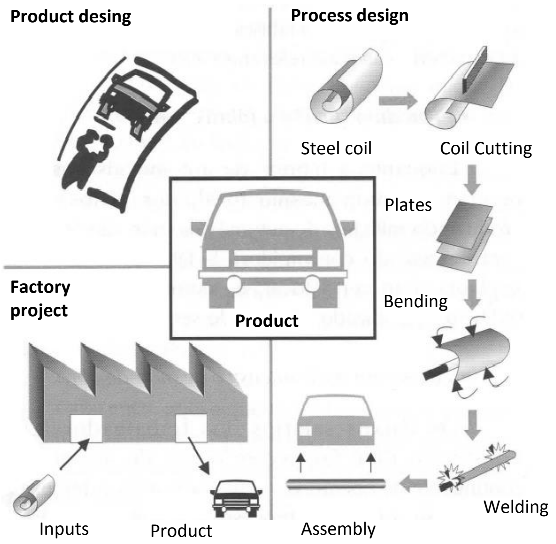

Figure 1: Industrial production of a car (Souza 2000)

Building construction industry should proceed the same way. But it is very common, in Brazil and in several parts of the world, to face very poor representations of production sites. One can point out several reasons to justify this situation: product stays in, and factory moves out; each workday is different from the others; etc. But the variability of the construction products and processes, leading to a very large range of production efficiency, safety, and quality indexes, can be pointed out as stronger reasons to justify spending technical efforts in deeper discussing construction sites. In this context, the authors have been working in both developing and implementing a method to be used for such a purpose.

Building construction sites usually hold a very large amount of workers and materials. One square meter of construction can demand from for about 5 to 100 work hours; such a construction labour productivity, associated to tight schedules, can lead to a very large crew (many times hundreds of workers) to be hosted in the site. Bathrooms, dressing rooms etc. should be available; and also organized work areas should be there to provide good work conditions to guarantee work efficiency and safety. One square meter of a building weights for about one thousand kg; then, the amount of materials to be stocked and moved along the site, and the ways to do that, are special topics to be addressed by construction managers.

The authors, concerned with the necessity of improving labor productivity, material transportation logistics and workers safety in the site, and based on their personal experience and literature about the theme available at that time, proposed a method to deal with site layout planning. During several years a textbook presenting the method was adopted in several construction management disciplines in Brazil as the basic approach to discuss site layout. The author's professional experience, along the last years and more than 50 construction sites studied, lead them to propose the application of such a method stressing three main discussions: construction phases; transportation systems; and site layout. The improved approach has been used in several construction cases and it is been useful to help discussions about improvement of labor productivity, logistics and safety construction (Figure 2)

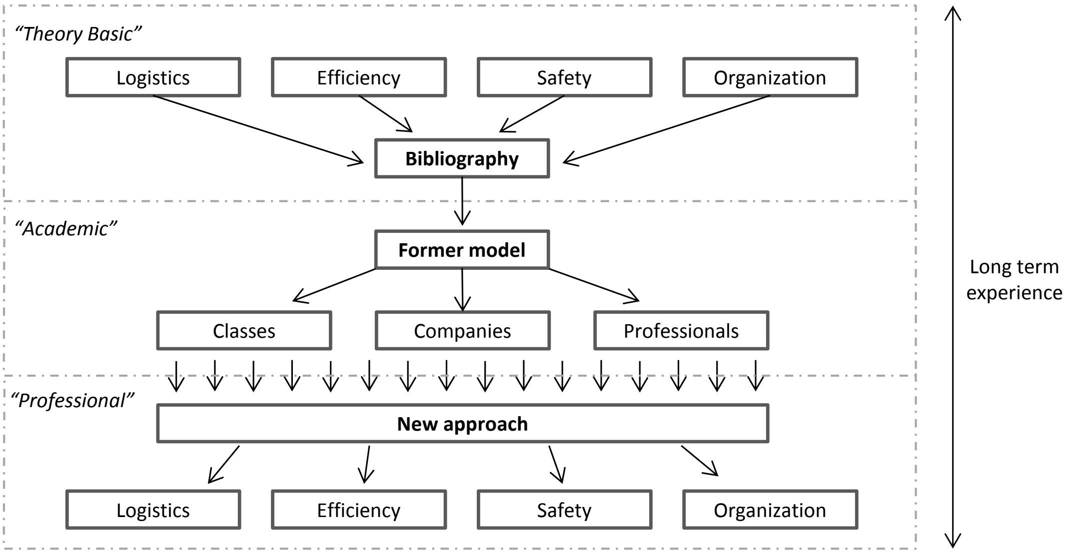

Figure 2: Author's experience and new approach

2. Theory about site layout

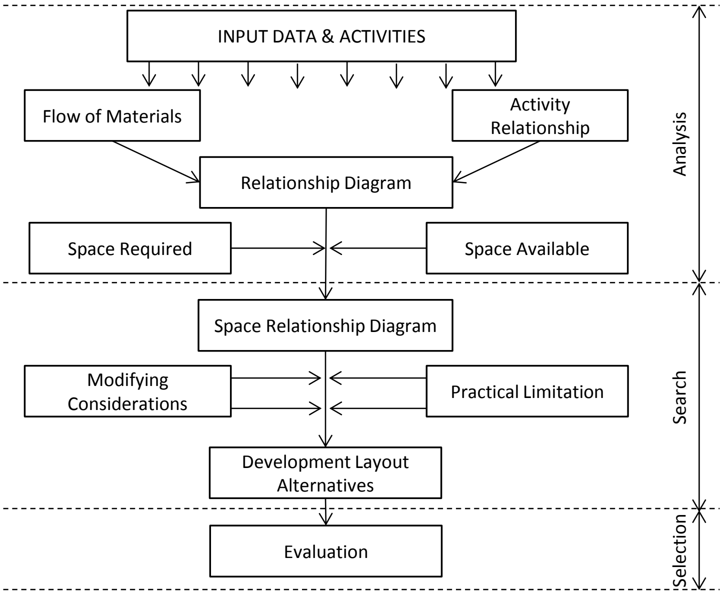
Table 1 presents the authors understanding about how to deal with site layout planning. Unfortunately, to deeply discuss building construction conception, differently from other design subjects, is still new for the contractors in Brazil.

Table 1: Site layout planning approaches (adapted from Souza 2000)

Questions about the design process	***Incorrect posture***	***Correct posture***
How to design?	*From personal criteria*	*From pre-set criteria*
When to do it?	*When you need*	*Preferably, before the work start*
Who designs?	*Who is around when the decision has to be made*	*Set of people that reflects the ideas of both the management and the workers*

Authors first experience in trying to establish directions to design construction sites was based on the ideas proposed by Muther (1973) in his book. Muther proposes several tools to help conceive a factory layout. For example, Figure 3 presents a diagram to define the factory areas to be closer to each other.

Figure 3: Defining area relative proximity importance (Muther 1973)



The steps related to the project process, such as, preliminary information and definitions regarding the process technology and demands for physical resources and spaces inside the construction site, have already been exploited enough by other authors, such as Parker & Oglesby (1978), Peurifoy & Ledbetter (1985), Souza (1993), and more recently, Andayesh & Sadeghpour (2014) who did comparative study of different approaches for finding the shortest Path on construction sites.

During his academic work, the main author of this article also contributed to the studies on construction site guiding some thesis dealing with site layout planning. Birbojn (2001), for example, listed all the site "elements" (parts) one site design should address presenting criteria to orient designers to choose among several alternatives they have to define each element. Table 2 shows the site elements classified according to Birbojn.

Table 2: Site elements types (adapted from Birbojn 2001)

Site elements	***Examples***
Related with production	*Central procession unit, production site…*
Support of production	*stocks, warehouse…*
Transportation system	*lifts, tower cranes…*
Administrative support	*offices, reception…*
Living space	*sanitary facilities, canteen, ambulatory…*

In such a context, authors like Handa & Lang (1988) described sampling elements considered necessary for the operation on construction sites and, through observation of these elements, developed a checklist for the projects evaluation containing weights for each item to be evaluated.

Another research advised by Souza, Maia (2003) considers a site designer goes through different phases in the conception processes and indicates that some of them demand more a mathematical work than a creative effort. He also proposes some directions to help the creative phase of the site layout planning. Figure 4 summarizes some of his directions.

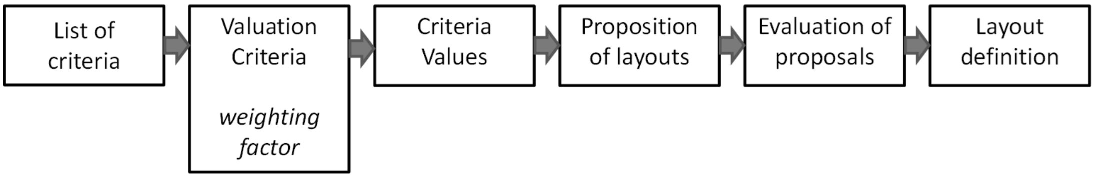


Figure 4: Direction to help creative job in designing site layout (Maia, 2003)

The compatibility between the phases of construction can be done with adjustments to positioning of elements, or changes of schedules, as Zouein & Tommelein (1992) did, aiming at reducing changes in the physical arrangement.

In order to help improving site layout planning implementation, Souza (2000) proposed a step by step method for new site designers. Figure 5 shows a flowchart discussed by Souza in his book.

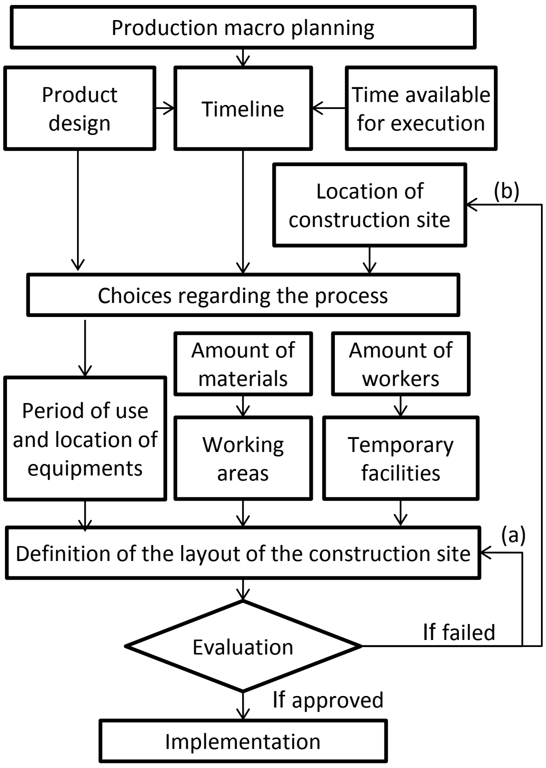

Figure 5: Sequence of site layout planning activities (Souza 2000)

Ideas proposed by Souza (2000) were used in several courses dealing with Construction Management, both for undergraduates and graduates. Some Brazilian researchers, as De Freitas & Santos (2009), tried to facilitate the use of these (and other) ideas leading to the site layout designing "by offering computer resources to help in their decisions making process and to visualize the spatial distribution of the elements in the construction site". Other countries researchers also tried to help stablishing a routine to design site layout in a similar way. Tam & Leug (2002) uses TI to import data to be used in the decisions and believes 3D visualization is very useful in discussing layout. The same authors and also Khalafallah & El-Rayes (2006) also presents algorithms to help some decisions, as for example to evaluate materials transportation cost.

The authors believe TI can help a lot not only with site layout planning but also in several others areas of construction management. But they also believe all these tools just can really be implemented if the process as a whole in defining site layout is understood. Based on the ideas one can see in Figure 5, the authors participate in real site layout planning activities during several years. In their professional experience, they have success whenever a representative group of the construction managers of the site being designed were able to participate in a process where 3 main issues (named "steps") were discussed and decisions were taken about them. These three needed decisions are described in the next item. But the authors believe that: 1) sequence of activities to produce one building extremely influences site layout best solution; 2) materials transportation is an issue to be addressed but there is more than one good solution to provide transportation, and to find the best choice demands interactions with the other 2 steps; 3) locating the several elements (working and nonworking areas) is something that demands more than architectural skills, for example to take into account manager can even change technology or supply politics to help finding better solutions for layout.

3. Proposed method

3.1. General description

The method was created based in a long term research and implementation effort, in a "back and forth" experience type. The academic studies and the opportunity to implement them in several real cases molded the nowadays method. In a very simple description, the new method uses the old ideas (see Figure 5) with an emphasis on the 3 commented aspects steps: construction phases understanding in terms of site demands; using mathematical models to determine the best transportation system for each case; and approaching architectural prescriptions both for working areas and temporary facilities to be built. Although a strong interaction among them occurs, the 3 aspects can be seen as 3 steps to reach the main goal, that is, discuss site layout before the construction activities begin.

Then, the main steps (Figure 6) to face a new project production conception are named: a) construction phases definition; b) macro logistics; c) site layout.

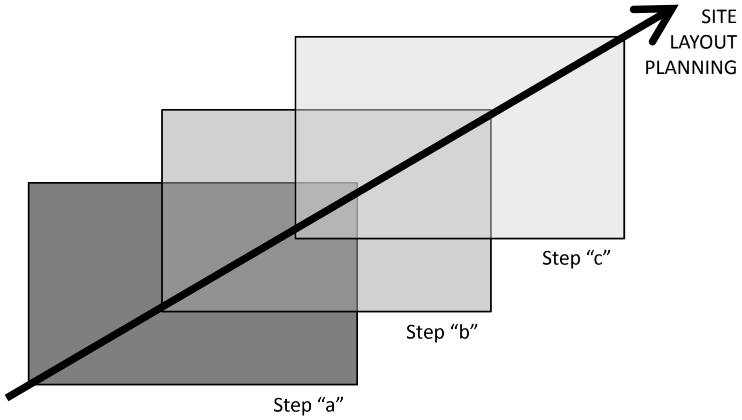

Figure 6: The three steps of the new approach to design site layout.

In step "a" the product as a whole is broken into parts to be produced in a certain schedule; each part is described in terms of its demands in terms of workers, materials and space. In step "b" the transportation systems (a group of machines/tools, varying in terms of type, quantity, location, and process of use) are defined, varying for each phase of the construction schedule. Step "c" is the one where creativity is more present; different architectural solutions are proposed to face resources demands and transportation prescriptions, both in terms of working areas and workers facilities.

3.2. Examples of the steps

3.2.1. Step “a” – Production Macro Planning

Considering the construction of a single building, Figure 7 exemplifies different plans of production that can be followed. One can plan to produce the tower as a whole before dealing with periphery; the opposite can also be planned; and a mix of the two approaches may constitute the plan to be chosen.

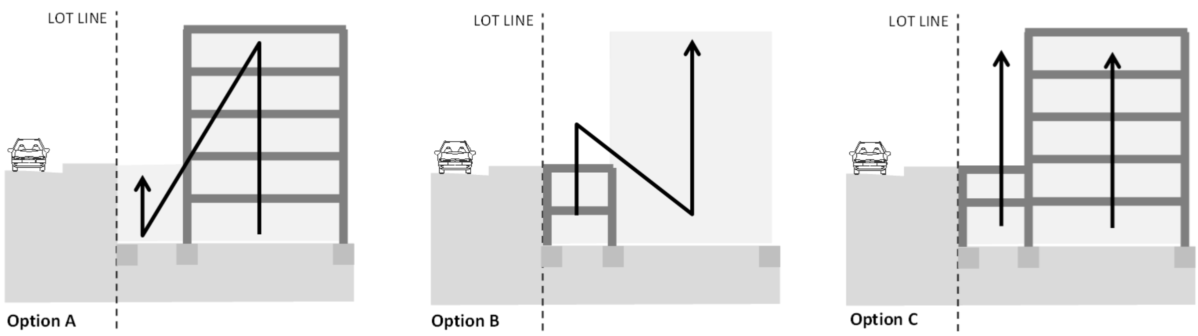

Figure 7: Example of distinct production macro plans for the same building to be built: a) tower before; b) periphery before; c) tower and periphery simultaneously.

Figure 8 presents a real example where plan “b” was adopted instead of plan “a” (to excavate from the back to the front portion of the site; and the same in order to latter produce foundation, steel reinforced concrete structure etc.) which is usually adopted by construction planners. The project holds three towers located in a relatively narrow site with just an only access (a very crowed by cars avenue near tower 1). Plan "b" allows the area of tower 2 to temporarily host the rebar working area avoiding material stocking crash.

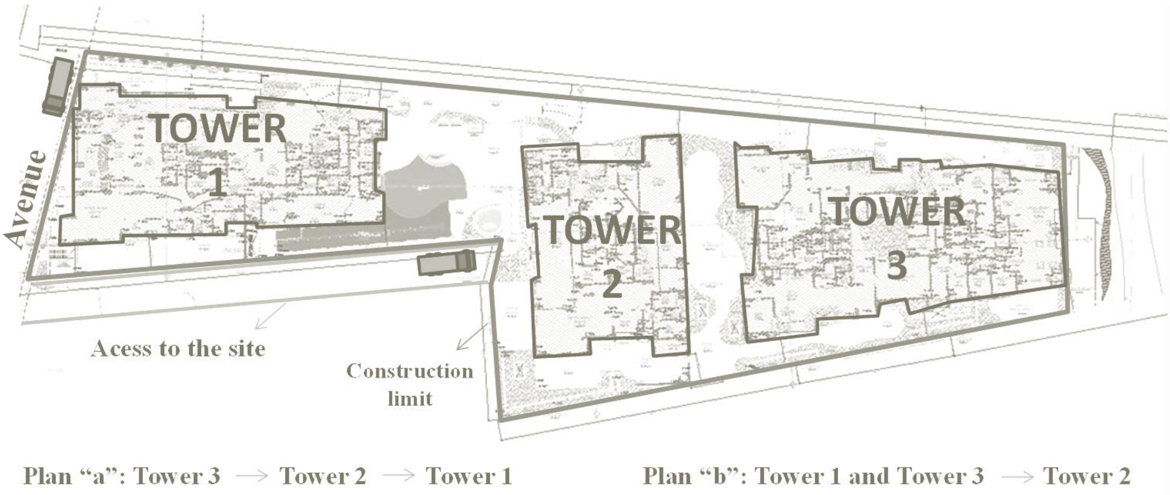

Figure 8: Project with three fifteen-story apartment buildings in Rio de Janeiro state- Brazil

3.2.2. Step "b" – Transportation System Definition

Material moving usually evolves several repetitions of a cycle, described as showed in Figure 9, with 4 parts: beginning, going, finishing, and return. The total time to completely move an amount of materials is defined once one knows the total amount to be moved, the quantity it is moved each cycle and the time of one cycle. More than this simple model, delays should be considered to calculate the capacity of a certain transportation system.

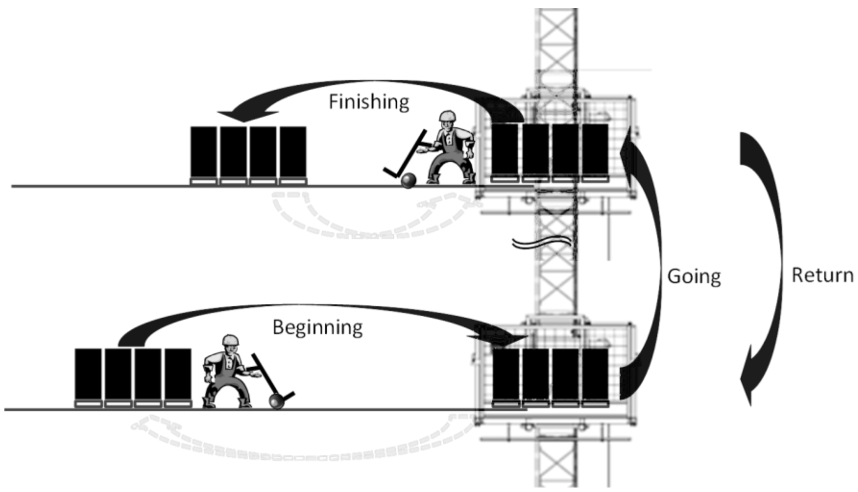

Figure 9: Cycle of materials transportation.

Once one knows the quantity and type of transportation equipment to face calculated demands, it is necessary to provide an appropriated location for them in the site. Figure 10 shows tower cranes (fixed and mobile) location in a multiuse (shopping mall and corporative office building) project in São Paulo – Brazil.

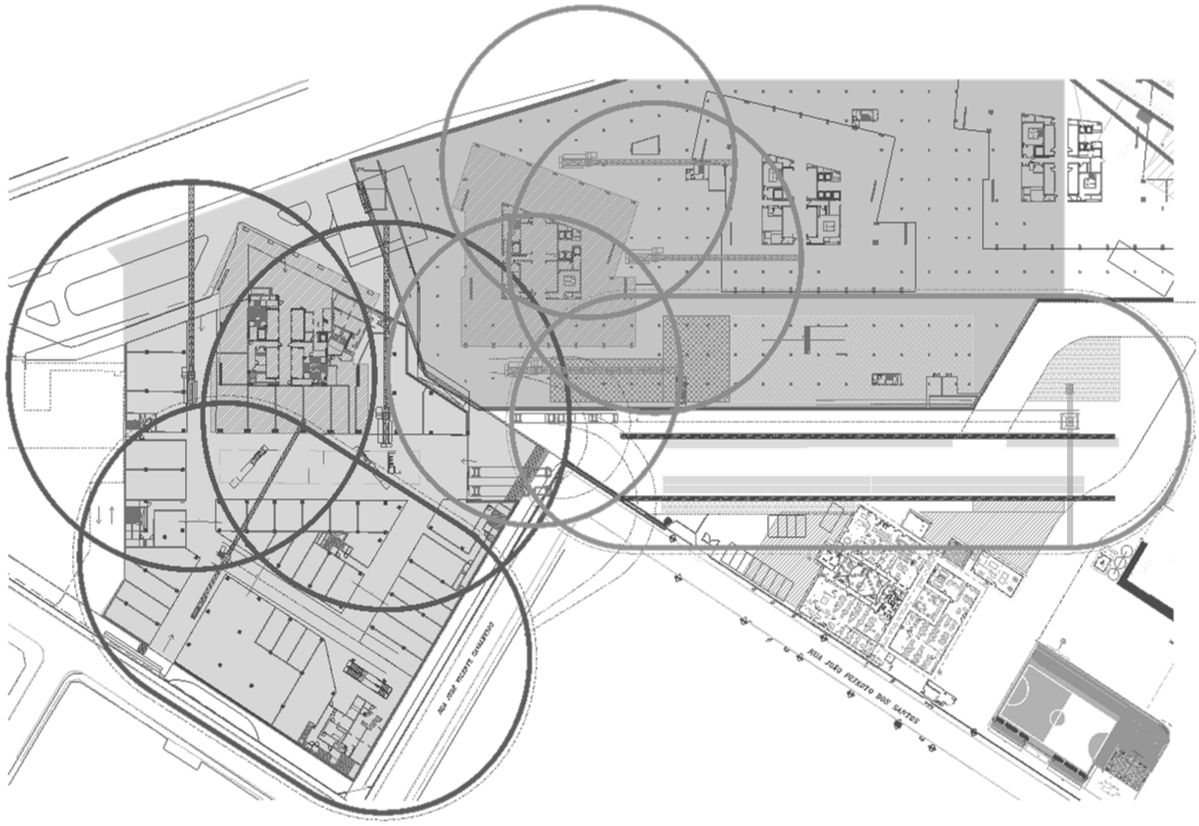

Figure 10: Location of the demanded tower cranes in a multiuse project site in São Paulo state.

3.2.3. Step “c” – Site Layout Drawing

Once site layout varies almost continuously (accordingly to the construction phases), some drawings are necessary to represent it. The drawings should both represent the working areas and temporary facilities for the workers. Each area can be represented as a “piece in the whole design” (“overview” of the site elements) but also it can be showed in detail.

Figure 11 presents an overview, in the beginning phase, for a residential two tower project where one can see the representation of several working areas, but also the access for trucks and even the place used to sell apartments.

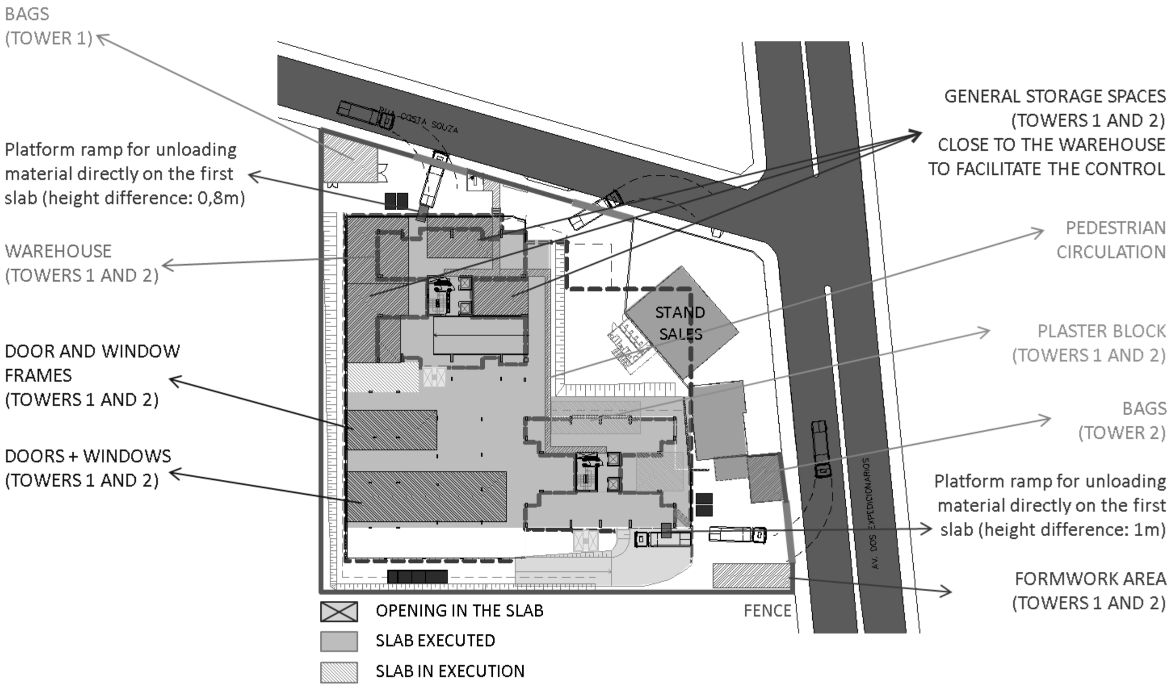

Figure 11: Overview site drawing, in the job first phase, for a residential project in Ceará state – Brazil.

4. Conclusions

This paper summarized a method that has been used in several Brazilian projects. The ideas here described were firstly defined in some academic researches; later, these ideas were used in real cases and there was a kind of improvement, both simplifying and fulfilling the directions to help designing the sites. Simplifying the steps to discuss site layout planning allowed more site managers participation what, in the authors opinion, increase de number of construction projects working with site layout designing. The method has being successfully used in a varied type of projects; from an unique house construction to a very huge multiuse group of high rise buildings. In terms of demanded research, the authors believe TI can help, but they recommend an emphasis in improving methods tools that gather together decision related to the 3 described steps.

Abstract

The need to manage and coordinate design has been recognized in different industries, including construction. However, teams need to have a shared language, which requires a design framework or in other words ontology, providing a terminology, principles and methods. Systems thinking approaches have been used in variety of design ontologies, here we have focused on the Domain Theory (DT). The purpose of this work is to understand how a common design framework aids the design inquiry and management. For that the DT is outlined, its implications to construction are reviewed and a case study as a main method is carried out to illustrate the effectiveness of this design theory for practice. The DT provided the common framework for studying end users, their needs and requirements based on their business operations. Also, the DT supported the design team in understanding the purpose of verification and validation. Results indicate that the common theory reinforced focusing on key parameters, issues and design requirements. However, outcomes also illustrate that system approaches tend to be resource intensive, requiring a more thorough analysis up-front.

Keywords: Domain Theory, design domains, technical activities, organs, structure

1. Introduction

The need to manage and coordinate design has been recognized for some time in industrial product (artefact) development (Farr, 1966), mechanical engineering (Andreasen, 1980), architecture (Emmitt, 2010) and also in engineering design for construction (Ballard and Koskela, 1998). The main reason for these developments is the division/disintegration of master builder into dedicated disciplines as the body of engineering design knowledge and expectations to efficacy have rapidly increased throughout the last three centuries (Kranakis, 1997, Reed, 2009). This has increased the complexity of construction projects and thus, the need for more thorough cooperation, coordination and management of engineering design processes thorough effective communication (Kleinsmann, 2006).

For the latter, design teams need a common language, such as a Domain Theory (DT) (Andreasen et al., 2014). Andreasen (2011) defined 'domains' as a set of dedicated views onto a product:

activities, organs and parts. These are used as the skeleton of a procedure for the product development/design. Domains consist of entities; e.g. the activity domain is determined by the user's application of the product, which together with the user experience and usability, to satisfy the initially unsatisfied need. Thus, the DT is an ontology, a common modelling framework, providing the viewpoints and vocabulary to represent the knowledge needed in product development.

An explicit and common modelling language allows transforming mental models into explicit models that can be shared among designers (Erden et al., 2008). Defining the domains, entities and the types of relationships can serve the purpose of developing a theoretical and conceptual model for engineering design coordination and management. Moreover, a consistent ontology supports the development of computing technologies and helps avoiding mistakes due to the neglect of some domains (Gielingh, 1990).

The aim of this research is to understand how formal design framework aids the design inquiry and management. More particularly, here we review the Domain Theory and its implications into practice (Andreasen et al., 2014, Howard and Andreasen, 2013). In the first part of this paper, a theoretical framework of DT is outlined; in the second part, the implications to construction industry are summarized; and finally, a case study, informed by the DT, is compiled to illustrate the importance of design theories.

2. Methods

The purpose of this study is to understand the implications of a common design framework (Domain Theory) to design practice. Thus, this research aims to answer to the following questions: How does the common design framework aid the conceptualization of design solution from users' perspective? What implications does the framework have on design team and process? For that a qualitative case study method is used to acquire context-dependent knowledge (Fellows and Liu, 2009). The lead author of this article participated in the development of new warehouse concept for small and medium sized businesses dealing with wholesale, retails sales, services or combination of these. This work focuses on the early stages of design and processes for developing a new concept for warehousing.

3. Engineering Design Terms and Frameworks

Across industries, several design researchers have tried to propose a unified definition for engineering design. Here, we start with the definition proposed by Evbuomwan et al. (1996):

> "The process of establishing requirements based on human needs, transforming them into performance specification and functions, which are then mapped and converted (subject to constraints) into design solutions (using creativity, scientific principles and technical knowledge) that can be economically manufactured and produced."

This definition succinctly illustrates the subject and the content of engineering design and three aspects are clearly visible. First, designers work on a variety of aspects during design process:

needs (voice of the customer), performance requirements (required, expected and actual behavior), functional descriptions, structural descriptions, and production/manufacturing processes. Secondly, engineering design can be viewed as a process, using different modes of reasoning, including regressive vs. deductive (backward and forward), decomposition vs. composition (breaking down and putting together) and transformation (transferring problems between abstract and particular) (Koskela et al., 2014). Thirdly, design is between thought and object (Bucciarelli, 2002), aligning three aspects of facilities, including user needs and requirements, design solutions and production processes.

3.1 Domain Theory

Several engineering design frameworks have been developed based on the systems thinking approach, such as the DT by Andreasen et al. (2014). DT consists of several models and concepts for understanding and researching design practices. The basic domains in DT include: technical activity, organ and part (structure). Andreasen et al. (2015) define the technical activity as the user's application of the product (use functions) for fulfilling the unsatisfied need. A use function is an activity of the user to utilize the product for performing certain action. Chen et al. (2015) define a need as a subjective desire of a person to change a problematic conceptual environment into a desirable one. The organ domain is the set of functions, the means of a product, displaying a mode of action (realization of function) and its behavior (properties). Part domain consists of components as an elementary material system, making-up an organ, realizing the organ's mode of action by the part's physical states and interactions. Thus, an artefact is defined by its structure, describing the anatomy of components, properties and relationships.

Properties of the systems and components are divided into two categories, describing the product structural characteristics (form, material, dimensions and surfaces) and behavior (derived from structural characteristics) (Andreasen et al., 2014). Characteristics are a class of properties of an object that define the means by which the object's behavioral properties are realized (Albers and Wintergerst, 2014). The behavior reveals when product is deployed by the user(s) in its context for use purpose and processes. In engineering design literature, behavior is characterized by successive states, including manifestations and value of the properties of the system in response to its environment and the received stimuli (Albers and Wintergerst, 2014).

When a product is deployed it contributes to the transformation of operands such as material, energy, information and/or biological objects. The properties of use functions in relation to the operands are described by their input and output states; the necessary effects from the operators, their nature, their state and how they lead into contact with the operands; and the active environment (Andreasen et al., 2014). The organs are based upon physical, chemical or biological phenomena. When stimuli act on the organ in its context, it delivers an effect. In other words, organs are also called *wirk* functions (Hubka and Eder, 1996, Albers and Wintergerst, 2014), which is a statement about what the product does when in operation (Howard and Andreasen, 2013).

Also the structure and its components are active and interact with each other through their assembly interfaces (Howard and Andreasen, 2013). Components are related to the *wirk* functions, which are based on natural (physical, chemical and biological) phenomena. A part interfaces with other parts and its surroundings, creating the effects of the part. Therefore, the DT defines the domains, its entities and relationships to describe the practice of engineering design.

Andreasen et al. (2015) have also described the engineering design process as a progression throughout the domains in DT. They define the engineering design process as a causal chain: user need > use activity result > determination of use activity > determination of the product's effects and functions > determination of organs and organ structure > determination of parts and part structure. However, in practice, design is not a linear process from needs to structure, it is rather a top-down and bottom-up approach simultaneously (March, 1984), meaning that problem and solution are coevolving throughout the design process.

3.2 Summary of the Domain Theory

The DT, initially developed based on the Hubka's Theory of Technical Systems, distinguishes between use functions (e.g. write text) and *wirk* functions (e.g. deposition of graphite onto the paper by means of pressure and friction) (Howard and Andreasen, 2013). This shows that designers do not only designate a product's behavior or mode of action but also the use activity of the end user. Secondly, the DT differentiates two types of properties, static structural characteristics as means for realizing the objectives and behavior (state variables) corresponding to the stimuli and changes in the environment. Thirdly, design is a process, moving from the need to the description of a structure (part domain) for delivering the expected effects (behaviors). Thus, design is a modelling process for establishing the network of connections between entities in different domains through the expected behaviors to be actualized.

4. Conceptualization of an Engineering Design Framework for Construction

Essentially, buildings are designed to facilitate users' personal or business operations. Space as the functional unit facilitates the satisfaction of user needs. In this work we consider the activity, organ and part domains of DT as a common denominator for design processes and disciplines. In following sections, the content of these domains are discussed in detail.

4.1 Activity Domain: Deployment of Facilities for Value Creation

As in the theory of domains (Andreasen et al., 2015) or proposed by Pennanen (2004), the first domain to be considered is the user process domain. This is an activity-based approach for decomposing client processes (personal or business) into user activities/sub-activities and their properties that realize the client's goals and thus are value-adding. For example, in office building the activity 'meetings' can have these properties: type of an meeting, types of participants, number of participants and usage of equipment (projectors, tables, chairs etc.). Currently, this tends to be considered only informally in the design process (Pikas et al., 2015). Thus, in the activity domain, use functions are defined as interaction with the artefact.

4.2 Organ Domain: Space as a Functional Unit

The user activities, their nature and resource requirements become the basis for defining the environment and its facility centric functional organs to be decomposed into sub-functions. This is typically articulated in the project brief, including information about the area (unit of area per room/person), dimensions (e.g. ceiling height), indoor climate (e.g. temperature, air exchange type and volume, air movement speed, cooling, heating and control of indoor climate), acoustics, lighting, electricity, water supply, sewage and use of equipment. It describes the facility consisting of functional spaces and its sub-functions, some required as resource for activity and others determined by the design decisions (Pennanen et al., 2005).

However, the articulation of spaces in the project brief is a complex activity, where form and use function of the building play the main role in determining how spaces should function, laid out and utilized. Required spaces affect many different aspects of the building, including its form, layout, utilization and spatial planning (Mayouf et al., 2014). Moreover, in a building program, expected behaviors of functions and structures are determined (e.g. air exchange rate). Thus, the completed building program, even though still subject to changes in later stages, is the basis for engineering design process. Koga (2010) defined functional decomposition as value engineering in Integrated Project Delivery, or in other words functional analysis.

4.3 Part Domain: Linking Functional Requirements to Structural Description

Design theoreticians have considered this as the kernel of the design process (Andreasen et al., 2015, Suh, 1998, Kroes, 2002). In schematic design, architect analyses the user needs and translates these into functional requirements (spaces and its sub-functions) and expected behaviors (temperature level to be maintained) as a basis for design conceptualization, and syntheses of the form based on selected technologies and materials required for meeting the client needs. The form defines the internal and external spaces, a composition plan for the totality and the details (relationships), social and economic issues, and a framework for human interactions (Andreasen et al., 2014). According to Hubka and Eder (1996), form can be interpreted and modelled as geometry. Other main structural characteristics include the materials, technologies and dimensions, determined to meet the expected behaviors of the structure. The outcome is the design concept describing the system architecture and its division (structure, HVAC, MEP etc.). Each system consists of a number of components designated during the embodiment of functions and expected behaviors, and its configurations and connections (Ullman, 2009). Particularly, it is the selection of components and their physical characteristics that determine the actual behavior of a system and the best fit with the requirements of the project brief. For example, the architect can link a ventilation unit to the requirement of minimum air exchange rate in a space.

5. Case Study for Illustrating the Implications of Domain Theory

In this section, a case study is compiled to illustrate the importance of domains and their entities; particularly, how the design ontology informs the design process. One of the largest Estonian companies, in the field of logistics parks and warehousing services, is looking for new opportunities for expanding their business services. Until now they have focused on large logistics parks, but they are planning to start providing warehousing services to small and medium sized vendors, service providers and trade companies. They were interested in developing a new warehouse concept that can be detailed for a specific parcel. In this sense, it can be compared to product development in industrial engineering. In the following, a short summary of the results and key findings are given.

5.1 Design Development Process

Largely, the design development process was divided into three steps: I observation of existing solutions and user needs; II design conceptualization; and III product concept development. In the first step all similar existing facilities were mapped in and around Tallinn, Estonia, and ten existing facilities were selected by the project team for closer study. Then the team, including client representatives, the architect, the design project manager and the lead author of this article, paid a visit to these ten facilities during a period of two and a half days. The result of this was 20 page report, summarizing the problems, existing solutions, main users, use activities and user needs/requirements. In the second stage, the report developed in the first stage, became the basis for conceptualizing the product and articulating the design task. The team avoided compiling heavy documentation, instead through several iterations a two page design concept paper was compiled as a basis for schematic design. The third step, product concept development took place over many weeks in an iterative manner. The architect proposed concepts, which were discussed within the project team. The final outcome was the concept for modular and flexible combined warehouse, office and service spaces.

5.2 Observation of Existing Solutions and User Needs – Activity Domain

As a part of a activity domain, ten sites were visited and users were questioned regarding solutions and their satisfaction. The following are the main observations:

- **Complex nature of the client:** All observed companies were importing goods and depending on the type of a product, these companies were either doing wholesale, retail and/or provided product related services (e.g. a tire shop), determining which kind of functional spaces were needed. Overall the following target client categories were identified: wholesale, retail sales, product related services or combination of these.
- **Typical spatial layout:**
    - Average space area per company was 317 m^2, including either storage, office and show rooms or combination of these. However, the distribution of spatial area

varied remarkably, and excluding one very small company from the sample, the average area increased to 568 m^2.
  - There was no correlation between the number of people working in the company and storage and/or show room area.
  - The average office area per person was 14 m^2. However, most of the tenants indicated that it was too much and more storage space was required. It was concluded that around 10m^2 of space per person in the office would be around the optimal solution.
  - Show rooms must be flexible and situated on the first floor, meaning companies who want can use it as a show room and others as an office space or service space.
- **Limitations of building form, layout and solutions:**
  - Offices spaces were designed throughout the whole building depth on different floors. The problem was that companies who had storage spaces on both sides of office spaces had difficulty moving goods between these two, they had to either transport the goods through office space or from outside. The latter is a problem in winter.
  - Several solutions had storage space through three floors, resulting in heights around 9-10 m. For workers responsible for storing goods this was a bad solution as it complicated the process of stowing goods.
  - Poor layout of office spaces as people working in these indicated that they did not have space for resting, eating or meetings.
  - Thresholds between show rooms and storage spaces hindered transporting goods.
  - The shelves were too long hindering the entrance and exiting through the transportation doors.
  - Also, several companies indicated that the transportation doors for transporting goods in and out from storage space were disproportional, either too high or wide.
  - Lights and ventilation ducts were crisscrossed with roof trusses.
- **Technical solutions:**
  - Observed buildings were made of precast concrete or steel structures, including sandwich panels, steel or concrete structural frames.
  - For heating and cooling mainly electricity based systems were used, e.g. air to air heat pumps.
  - Five buildings out of ten had skylights either in office or storage sections as the storage buildings can be relatively deep.

5.3 Design Conceptualization – Organ Domain

The observations within activity domain became the basis for articulating the goal and requirements. The main goal was to develop: “Modular, flexible, spatially optimal, cost and energy efficient combined production, service, storage and office building for small and medium sized wholesale, retail or service companies.” Table 1 defines the value structure for the project, defining the category, expected performance and constraints.

Table 1. Summary of concept categories and expected performance.

Nr	Category	Expected Performance
	Suitability	
1	Modular spaces	Space range per module: 200-600 m^2
2	Flexible storage and show room spaces for expansion	Movable internal walls and flexible building services
3	Effective form, spatial layout and stowing of goods	• Office spaces shall be along the front exterior wall of building • Storage spaces shall have optimal paths for the movement of equipment and transportation of goods • Office spaces must have small kitchenette and toilet on first and second floors • The width of the corridor shall be designed based on maneuvering radius of forklifts with lifting capacity of ≤ 1.5 tons. Expected width between shelves ≥ 3.2 m • For the maximization of storage spaces the optimal spacing of shelves shall have two or three corridors • Office space ≅ 10 m^2 per person • Size of the transportation doors: ≥ 2.8m height and ≥3 m width • Clean height of storage space under trusses: 6m (clean height for stowing is 4.5 m)
	Aesthetics	
5	Comfortable working conditions	Well-lit working spaces and aesthetical materials
	Sustainability	
6	Energy efficient	Cost effective energy efficiency solutions: minimum requirement is B-class (consider renewable energy)
7	Indoor climate control	Users have possibility to control indoor climate, heating, cooling, ventilation and lighting
	Durability	
8	Optimized structures and details	Cost optimized solutions of structures and details
9	Optimal maintenance costs	Highly enduring materials and maximum lifespan (50 years for structures)
	Construction Cost	
10	Construction cost	≤ 400 €/m^2 (target cost)

The overall preferred layout for the business activities is that goods are transported from behind and clients enter from front. The functional decomposition depends on the business function or main activities, which here were divided into four categories: **wholesale**, **retail sales**, **product related services** or **combination of these.** These categories became the basis for spatial decomposition as follows:

- **Office spaces**: must be aesthetical, comfortable, functional and well lit. Companies want to provide good working conditions to workers. The office spaces must have good layout, providing enough workspaces, kitchenette and toilet. Typically, companies with total space around 400 – 600 m^2 also need small meeting room.
- **Show rooms**: Not all companies need this type of space, those who need have varying requirements in terms of size. Thus, first floor offices spaces must be flexible, either be used as a show room, reception space for clients or as an office space.
- **Service areas**: Companies, who need service spaces, must have rooms two floors high. Some companies who provide services also provide shower and dressing room for workers.
- **Storage spaces:** In general goods can be divided into two groups: small and large by size. Thus, larger goods are moved with forklifts and smaller ones by hand. Companies need enough space between shelves to manoeuver with forklifts. Regarding the indoor climate, few companies had products that required controlled indoor temperature and humidity levels.

5.4 Product Concept Development – Part Domain

In this stage, architect prepared the first draft based on the selected concept, linking functional requirements to physical characteristics. The overall concept was a modular warehouse for different user needs. Modules were defined as rectangles in varying sizes, which were combined in different ways to form a whole building. However, the whole size of the building will depend on a specific site, zoning requirements and design requirements by the local government. The driving concept for the architect was “organized chaos”. A model was prepared in Graphisoft ArchiCAD to facilitate the conversation between the architect and the client. The starting point for the architect was the storage space with two or three corridors between shelves and with the size of the columns, initially 300 x 350 mm.

The second aspect that the architect had in mind was modularity, the proposed main module being 6 m x 6 m. However, the first module, including office spaces and show rooms, was 7.5m deep. The architect also had to consider the other constraints, such as transportation door width and height. For example, based on the size of transportation doors, the first floor windows were chosen to be of the same size. During this iterative process several layouts were proposed and in each iteration, the architect focused on a specific aspect. After a few iterations, the structural, HVAC and electrical engineers were involved, performing the basic calculations to verify the architect’s assumptions and proposed conceptual solutions for different systems. For example, the columns were changed to 400 x 400 mm due to the fire safety considerations.

The biggest challenge was to find appropriate solutions for flexible spaces, which was considered as an important innovation and a primary goal of the project. As shown in Figure 1, the end walls of each section are movable. The same is with the office and show rooms, however, these can be expanded only to right and left in respect to the front and back of building. Flexibility was required considering how to build lighting systems and building services in the way that these would accommodate the changes in the layout of the building. Therefore, the meters for measuring the energy consumption were designed to be placed to the beginning of every rentable section of the facility. Lighting systems were connected through outlets, in case of moving walls the connections can be moved as well from one outlet to the other. For same reason of flexibility, the floors for second floor were planned to be built of standardized prefabricated wooden frame panels and the interior walls of sandwich panels that can be easily assembled or disassembled.

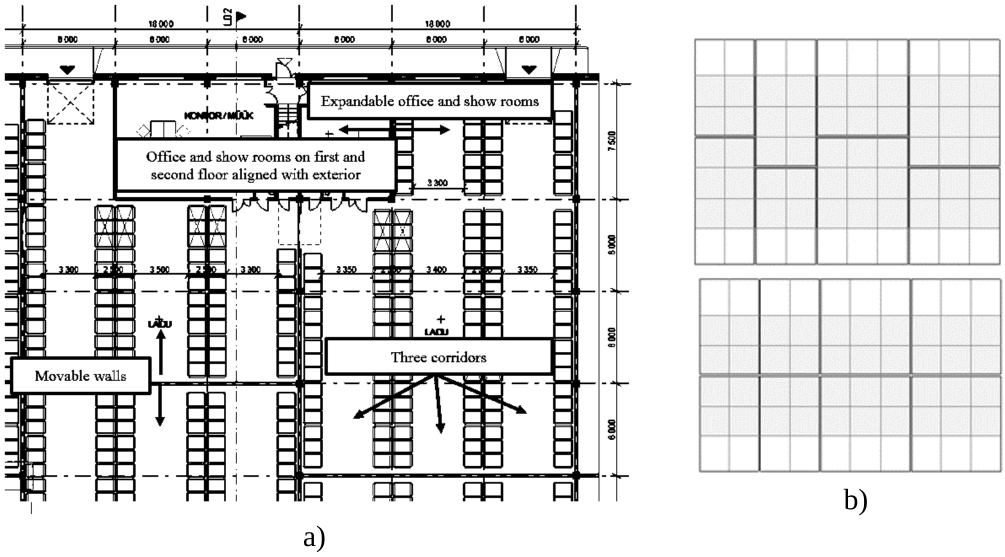

Figure 1. Combined storage, office, service and show rooms building: a) flexibility of spaces enabled by movable walls; and b) two examples of modules and composition.

At the end of the product development stage, one Estonian contractor was involved to validate the solutions from the perspective of buildability, and to make an early cost estimation. The model was used for quantity take-off and making buildability assessments. The target cost was set to 400 €/m^2, the contractor estimated 413 €/m^2. However, the team also figured that cost can be reduced by more detailed design and elaboration of technical solutions.

Furthermore, the client used the produced concept to validate the business model on the market. They used layouts and BIM based renderings to compile a fictive advertisement. Altogether, project got around 20 views on the website and three persons called and asked for more details. Although the interest could be considered low, it was also understood that organizations who are looking for new spaces are interested in facilities, which are already existing. The client confirmed the proposed product concept, and now the first project has been initiated.

6. Discussion

The case study, guided by the application of the DT, indicated the importance of a common design framework as a means for effective communication. Case study clearly indicates the content of the different stages: I stage as a part of activity domain was focused on observing existing solutions and user needs; II stage as a part of organ domain was for design conceptualization; and III stage as a part domain focused on the materialization of product concept. All involved parties agreed on the usefulness of common domains, entities and relationships. Furthermore, a clear articulation of project value structure, in terms of targets and constraints, facilitated the iterative design process. However, as the design team was busy with understanding the DT, the focus was not on design management, thus, causing the concept development to take three months more than was initially planned. Thus, this can also be considered as the main limitation of this research. In the future projects, design management aspects must be considered, including the implementation of Last Planner System and/or Scrum (from Agile Management) to plan, execute and control the design process by defining the information flows through pull mechanism. The other reason why this is particularly important is that currently the architect still tended to make many assumptions, instead of involving downstream engineers immediately to concept development. Thus, in the near future, the plan is to implement the cell layout for project design team, to facilitate real time communication and reduce the response time for request for information. The team also noticed that systematic approaches tend to be resource intensive, which currently is not a typical practice for the early stages of design. Thus, approaches such as Axiomatic Design theory, could be used to stage the design process by focusing on a key functional requirements and design parameters in each stage.

7. Conclusions

In this article, the DT and its implications for construction were studied through a case study. Answers for two questions were sought: How does the common design framework aid the conceptualization of a design solution from users' perspective? What implications does the framework have on design team and process? As for the first question, the DT provided the common language for the design team, a mental model for the design concept development. This means that the DT provided the common framework and reinforced focusing on key parameters, issues and design requirements. For the second question, the DT supported the design team in understanding the purpose of verification and validation. An example of verification was the involvement of structural and building services' engineers in the early stages of design, doing design review. However, the limitation of this case study was that the design focused solely on familiarizing with the DT, but not on the design management. The result was that the concept development took several months longer than was initially planned. Thus, in the future research, control methods must be implemented to maintain the schedule and avoid the architect's assumptions by using a pull mechanism.

Abstract

Depending on the user's perspective, a given reality can be represented in different ways and by different mathematical models. Service life prediction is a challenging task, due to the variability related with the degradation processes and the large number of variables that affect the buildings' life cycle. There are different possible approaches to the service life prediction of natural stone claddings. In this study, different models for service life prediction are proposed, grouped in four methodological families: i) deterministic models; ii) factorial models; iii) stochastic models; and iv) artificial intelligence-based models. These different approaches are established based on an expert survey of 203 stone claddings (directly adhered to the substrate), in-use conditions. This survey is performed by the authors on natural stone claddings in current buildings (housing and commerce) located in the Lisbon area, in Portugal. A comparative analysis is performed, through the comparison between the results obtained by each model and the data collected during field work, corresponding to the real degradation condition of the stone claddings analysed, in order to evaluate the sensitivity, specificity and accuracy of the models. Once the prediction capability of the proposed models is evaluated, a multi-criteria decision analysis is performed in order to compare the different models applied to service life prediction of stone claddings. This analysis intends to guide the choice of a particular model for a given application based on a set of decision criteria. Also, the main motivations and goals of the stakeholders are analysed, leading to different weights in the decision criteria. In real world, a rational process of decision-making incorporates subjective criteria and different "points of view". In this study, the multi-criteria decision analysis comprises two perspectives: the planner's point of view (who defines the model, e.g. the designer); and the user's perspective (who uses the model, e.g. a real estate manager). The essential parameters that may influence the selection of a given model are analysed. Based on the comparative analysis of different service life prediction models, some recommendations are made, concerning the advantages and limitations of the models proposed.

Keywords: Service life prediction; natural stone claddings; comparative analysis.

1. Introduction

Currently, there are different possible approaches to the service life prediction of natural stone claddings (directly adhered to the substrate). Naturally, different methods lead to different results, with (Lourenço et al., 2007): i) different levels of complexity; ii) different levels of availability; iii) different processing times, ranging from the instantaneous output of results to models that may require hours of computer processing; and iv) different costs. This study presents a review of different methodologies for service life prediction applied to natural stone claddings, grouping these approaches into four methodological families: i) deterministic models; ii) factorial models; iii) stochastic models; and iv) artificial intelligence-based models. All the proposed models lead to accurate results and are able to describe the degradation phenomena of stone claddings. Therefore, a comparative analysis is performed in order to evaluate the applicability of each model. The comparison between predictive models must take into account some basic principles: i) the model should be adjusted to the data, with a significant explanatory power, and must cover all the relevant aspects in the description of the phenomena under analysis; ii) it should respect the parsimony principle, i.e. in the presence of two models equally accurate, the model with lowest number of parameters should be chosen; iii) the model parameters should be easily interpretable; iv) the model should be able to describe the behaviour of the entire population, i.e. should not be over-adjusted to the sample, and must be able to predict the behaviour of new case studies, which have not been previous analysed by the model; v) it should be easy to apply, considering the ease with which the user understands how to use the model, the quantity and complexity of the data required for the model to work properly, and the software required and its processing time. Based on a set of different criteria, a multi-criteria decision analysis is performed, comprising two perspectives: the planner's point of view (who defines the model); and the user's perspective (who uses the model). Assuming that different stakeholders have different points of view, a sensitivity analysis is also performed in order to analyse the best model for different decision-making profiles. Based on the comparative and the multi-criteria analysis, some recommendations are provided, referring the advantages and limitations of the models analysed and thus allowing a more rational and informed selection of a service life prediction model concerning the purpose of the model and the planner's profile and the user's perspective.

2. Service life prediction models

In this study, 203 natural stone claddings (directly adhered to substrate) are analysed, in service conditions, surveyed through visual inspections. The overall degradation of stone claddings is evaluated through a numerical index, initially proposed by Gaspar and de Brito (2008), given by the ratio between the degraded area - weighted as a function of its state of repair - and a reference area, equivalent to the whole area of the façade with the maximum degree of degradation - expression (1).

$$S_w = \frac{\Sigma(A_n \times k_n \times k_{a,n})}{A \times k} \tag{1}$$

Where S_w represents the severity of degradation, expressed as a percentage, k_n the multiplying factor of defects n, as a function of their degradation level, within the range $K = \{0, 1, 2, 3, 4\}$, $k_{a,n}$ the weighting factor corresponding to the relative weight of the defect detected ($k_{a,n} \in R+$) according to the cost of repair (Silva et al., 2011), A_n the area of coating affected by a defect n, in m^2, A the façade area, in m^2 and k the multiplying factor corresponding to the highest degradation level of a cladding, as defined in *K* above, of area *A*.

To predict the service life of stone claddings it is necessary to define the instant in time in which they reach the end of its service life. However, this theoretical limit is not easy to define since it depends on a set of subjective criteria, varying according to time, place, user's needs and the building's context (economic, social, aesthetics, environmental or political). In this study, it is considered that a cladding with a severity of degradation higher than 20% has reached the end of its service life. This value was adopted based on the sample analysed and on a survey answered by the owner and users of the buildings analysed.

The different models described in the next sections include as explanatory variables the variables with higher statistical significance in the description of the degradation phenomena of stone claddings. The variables were selected using a sensitivity analysis and based on a stepwise technique described in Silva et al. (2012). All the proposed models include as explanatory variables age, distance from the sea and size of the stone plates, thus revealing a high relevance of these variables in the description of the degradation phenomena of stone claddings.

2.1 Deterministic models

Deterministic models use mathematical formulations and/or statistics, aiming to describe the relationship between the degradation mechanisms and the façades' degradation condition. These models, although being extremely effective in large and representative population samples, generally ignore the random nature of the phenomena under analysis. In this study, deterministic models comprise different types of regression analysis: i) simple regression analysis (degradation curves); ii) multiple linear regression; iii) multiple nonlinear regression. Simple regression expresses the loss of performance of façade claddings through a continuous function called "degradation curve". This curve can be graphically represented, where the *x*-axis represents the age of the stone claddings (assuming that age is the period of time between the date of the last intervention on the cladding and the inspection date) and the ordinate axis the index that expresses their global degradation (S_w). Equation (2) shows the result of the simple regression analysis performed.

$$S_w = 6\text{E}-05 \cdot A^3 - 0{,}0013 \cdot A^2 + 0.065 \cdot A + 1.538 \quad (2)$$

Where S_w represents the severity of degradation of the façade (%) and *A* the age of the façade.

The second model, multiple linear regression analysis, can be seen as an extension of the simple regression analysis that comprises more than one explanatory variable. Equation (3) presents the model applied to stone claddings with four explanatory variables. In the model's definition, a stepwise regression technique is applied, ensuring that all the assumptions concerning the statistical significance of the model are fulfilled.

$$S_w = 0.003 \cdot A - 0.429 \cdot S - 0.195 \cdot SS - 0.174 \cdot D + 0.772 \quad (3)$$

Where S_w represent the severity of degradation of the façade (%), *A* the age of stone claddings, *S* the distance from the sea, *SS* the size of stone plates and *D* the exposure to damp.

The third methodology is the multiple nonlinear regression analysis, which is similar to the multiple linear regression but uses a nonlinear function in the approximation between the model and the data. In this study, nine nonlinear models are applied: polynomial regression; Gompertz curve; Von Bertalanffy curve; Richards curve; Morgan-Mercer-Flodin curve; Weibull curve; Brody curve; exponential regression; potential regression - equations (4) to (12), respectively.

$$S_w = 4.033\mathrm{E}-05 \cdot A^2 - 0.080 \cdot S^2 - 0.083 \cdot SS^2 - 0.075 \cdot D^2 + 4.659 \cdot WR^2 - 0.069 \cdot O^2 - 4.213 \quad (4)$$

$$S_w = e^{-0.097 e^{-0.017 \cdot A + 1.440 S + 0.504 D + 1.058 SS + 0.553 O + 0.447 \cdot TS}} \quad (5)$$

$$S_w = \left(1 - e^{-0.05 \cdot e^{-0.011 A + 1.145 S + 0.0359 D + 0.74 SS + 0.299 TS + 0.366 O}}\right)^3 \quad (6)$$

$$S_w = \left(1 - e^{-1.896\mathrm{E}-04 \cdot e^{-0.018 A + 1.120 S + 0.938 D + 0.884 SS}}\right)^{1606351} \quad (7)$$

$$S_w = \frac{-76.557 + 1.756 \cdot \left(A^{1.249} + S^{-74.741} + D^{-32.849} + SS^{-49.303} + TS^{-53.132}\right)}{1594.935 + A^{1.249} + S^{-74.741} + D^{-32.849} + SS^{-49.303} + TS^{-53.132}} \quad (8)$$

$$S_w = 588.913 - 588.911 e^{-1.660\mathrm{E}-09\left(A^{2.863} + S^{-189.674} + D^{-107.606} + SS^{-164.604} + TS^{-216.957}\right)} \quad (9)$$

$$S_w = 1064.756\left(1 - 0.999 e^{-2.595\mathrm{E}-06 \cdot A + 4.148\mathrm{E}-04 \cdot S + 1.213\mathrm{E}-04 \cdot D + 2.060\mathrm{E}-04 \cdot SS + 3.013\mathrm{E}-05 \cdot TS}\right) \quad (10)$$

$$S_w = 7.478 e^{0.035 A - 1.501 \cdot S - 1.756 D - 1.777 \cdot SS - 1.062 \cdot TS} \quad (11)$$

$$S_w = 1.907\mathrm{E}-06\left(A^{2.718} + S^{-167.949} + D^{-102.858} + SS^{-152.310} + TS^{22.006}\right) \quad (12)$$

Where S_w represent the severity of degradation of the façade (%), *A* the age of the stone claddings, *S* the distance from the sea, *SS* the size of stone plates, *D* the exposure to damp, *WR* the exposure to wind-rain action, *O* the façades orientation and *TP* the type of stone. For the application of the deterministic models, the variables included in the models must be replaced by the numerical values presented in Table 1.

2.2 Factorial model

The factorial method is one of the main methodologies for service life prediction and is proposed in the international standard for durability (ISO 15686: 2000). In this method, the service life is obtained by multiplying a reference service life by the durability factors that influence the degradation process of the element under analysis. Equation (13) shows the application of this method to the service life prediction of stone claddings.

$$ESL = RSL \times A1 \times B1 \times B2 \times B3 \times B4 \times B5 \times E1 \times E2 \times E3 \times E4 \times F1 \times G1 \quad (13)$$

Where ESL represents the estimated service life, RSL the reference service life (68 years), *A* the type of stone, B1 the façade colour, B2 the type of finishing, B3 the size of stone plates, B4 the thickness of the stone plates, B5 the location of cladding, E1 the façades orientation, E2 the distance from the sea, E3 the exposure to wind-rain action, E4 the exposure to damp, F1 in-use conditions, and G1 ease of inspection of the façade. The quantification of the durability factors is presented in Table 1.

Table 1: Quantification of the variables included in the deterministic and factorial models

Durability factors			**Numeric value - deterministic models**	**Weighting value - factor method**
A1	Type of stone	Limestone Marble Granite	1.040 0.960 1.390	1.000 0.950 1.100

2.3 Stochastic models

These methods allow analysing the probabilistic distribution of the degradation condition of stone claddings over time and according to their characteristics. With logistic regression it is possible to establish the probability that each case study has of reaching the end of its service life according to its age or characteristics - equation (14).

$$P(Y = "End\ \ of\ \ service\ life") = 1 - \frac{1}{1 + e^{-12,743 + 0,188 Age}} \quad (14)$$

2.4 Artificial intelligence based models

Artificial neural networks (ANNs) can be seen as emulations of biological neural systems, gathering information through a learning process. ANNs "learn" from a set of input and output patterns concerning the degradation of stone claddings, and are able to predict the behaviour of new case studies. Using this model, the severity of degradation of stone claddings is obtained depending on the values of the explanatory variables and a set of coefficients defined according to the proposed formulation - equations (16) and (17).

$$S_w = h_0 + \sum_{i=1}^{4} h_i \, H_i \qquad (16)$$

$$H_i = \tanh \left(c_{i0} + c_{i1} \, F + c_{i2} \, S + c_{i3} \, SS + c_{i4} \, A\right) \qquad (17)$$

Where variables *F*, *S*, *SS* and *A* are respectively the type of finishing, distance from the sea, size of the stone plates, and age of the stone cladding, and coefficients h_0 to h_4 and c_{i0} to c_{i4} are listed in Table 2.

Table 2: Coefficients of the proposed formula

i	h_i (-)	c_{i0} (-)	c_{i1} (-)	c_{i2} (-)	c_{i3} (m^{-2})	c_{i4} ($year^{-1}$)
0	1.368E-01					
1	-7.461E-02	1.040E+00	2.079E-01	-2.551E-01	-1.675E-01	-1.294E-02
2	-6.571E-02	5.543E-02	-1.161E-01	-1.838E-01	-3.709E-01	-6.621E-03
3	8.618E-02	7.720E-01	5.671E-02	-2.963E-01	-1.034E+00	4.278E-03
4	-1.190E-01	2.495E+00	1.620E-01	-2.387E-01	-1.596E+00	-2.333E-02

Fuzzy models are especially interesting when the problem modelled is subject to uncertainties, and are capable of describing systems and realities naturally vague. Fuzzy models combine numerical precision to transparency in the form of linguistic rules, dealing with complex phenomena with better performance than conventional linear models. In this study, a fuzzy model is used to estimate the severity of degradation of stone claddings - equation (18).

$$S_w(x) = \frac{\sum_{i=1}^{C} \beta_i f_i(x)}{\sum_{i=1}^{C} \beta_i} \qquad (18)$$

Where $f_i(x)$ denotes the function assigned to each of the rules and β_i the value of the membership function associated with the set of conditions that describe the case analysed (Vieira et al., 2015). The fuzzy rules describing the local input-output relation are presented in equations (19) and (20).

Rule 1: If u_1 is A_{11} and u_2 is A_{12} and u_3 is A_{13} and u_4 is A_{14} then:

$$y_1(k) = 4.25 \cdot 10^{-4} u_1 + 6.00 \cdot 10^{-4} u_2 - 2.78 \cdot 10^{-2} u_3 + 1.38 \cdot 10^{-3} u_4 + 1.56 \cdot 10^{-2} \qquad (19)$$

Rule 2: If u_1 is A_{21} and u_2 is A_{22} and u_3 is A_{23} and u_4 is A_{24} then:

$$y_2(k) = 1.04 \cdot 10^{-2} u_1 + 1.29 \cdot 10^{-2} u_2 + 1.09 \cdot 10^{-1} u_3 + 5.24 \cdot 10^{-3} u_4 - 1.96 \cdot 10^{-1} \qquad (20)$$

Where u_1 represent the type of finishing, u_2 the distance from the sea, u_3 the size of the stone plates and u_4 the age of the stone cladding. The membership functions for each of the four input variables are shown in Figure 1.

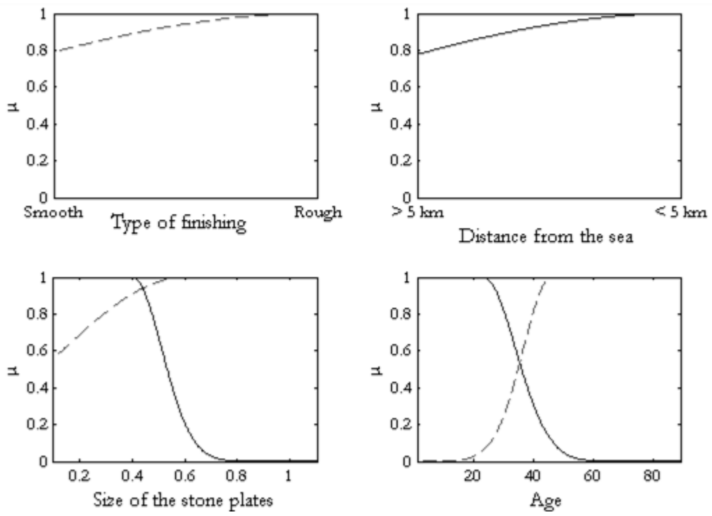

Figure 1: Membership functions for the first fuzzy model proposed

3. Comparative analysis of service life prediction models

All the proposed methods allow estimating the service life of stone claddings, leading to different results. The models present different characteristics; i) regression analysis and artificial intelligence based models are defined to obtain the estimated severity of degradation (S_w); in these models, to estimate the service life of stone claddings it is necessary to calculate the age of the façades corresponding to a S_w of 20%, corresponding to the end of service life of stone claddings; ii) stochastic and factorial methods are not intended to predict the severity of degradation of stone claddings - the first allows estimating the probability of each case study reaching the end of its service life and the second allows calculating directly the estimated service life of façade claddings. Table 3 shows the estimated service life obtained using each model, with the associated standard deviation. Furthermore, some statistical indicators are used to evaluate the performance of each model, namely: the Pearson correlation coefficient (r); the determination coefficient (R^2), the mean absolute percentage error (MAPE). Lewis (1997) refers that the MAPE can be used to measure the average relative size of the absolute prediction deviation as a percentage of the corresponding demand value; the author suggests that a value of MAPE less than 10% reveals a model with a potentially very good predictions. Besides these parameters, other indicators can be used to analyse the accuracy of the proposed models. In this study, ROC (Receiver Operating Characteristics) curves are used to evaluate the sensitivity, specificity and accuracy of the service life prediction methods. ROC curves are normally used to measure the performance of a diagnosis system; in this study, ROC curves are used to evaluate the accuracy of the models in classifying correctly the case studies that “reached the end of their service life” and the case studies that “not reached the end of their service life”. This test produces three relevant indicators: i) accuracy of the model - measure of the overall percentage of cases correctly classified by the model; ii) sensitivity - measures the ability of the model to correctly predict the cases that have reached the end of their service life; iii) specificity - measures the probability of the model assuming that a cladding has not reached the end of their service life, when it has really not reached that stage; iv) area under the ROC curve - varies between 0 and 1 and measures the classification capability of the model (models with an area under the ROC curve below 0.5 show no discriminating power). Concerning the fuzzy logic model, it is not possible to estimate the model’s sensitivity, since in the sample test (randomly selected) none of the case studies has reached the end of its service life.

Table 3: Estimated service life and the statistical indicators used in the analysis of the predictive ability of the proposed models

Model	Average ESL (years)	Standard deviation (years)	*r*	R^2	MAPE	Sensitivity	Specificity	Accuracy	Area under the ROC curve

4. Multi-criteria analysis of service life prediction models

Table 4 shows the description of the criteria applied in the multi-criteria analysis performed.

Table 4: Description of the criteria adopted

Criterion	**Description**	**Analysis of the proposed models**
P1	The learning process includes: i) a comprehensive survey of the state of the art about the statistical tool underlying the prediction model; ii) an analysis of the potential and applicability of the model to service life prediction; iii) an evaluation of the results that may be obtained and the best way to achieve those results; iv) the model experimentation and statistical software necessary for its implementation; v) the ability to deduce the results.	The simpler method is simple nonlinear regression, which is based on fitting a mathematical equation to a data set. Fuzzy logic is the most complex method, with a time-consuming learning process and whose theoretical assumptions are more intricate.
P2	In this criterion the time necessary for the creation and processing of the model is considered. It is assumed that the researcher knows exactly what is to be achieved with and how to proceed to model each approach.	Simple and multiple linear regression are the models whose results are obtained immediately. Artificial intelligence based models are the most time-consuming approaches.
P3	In this criterion, two parameters are analysed: i) availability and prominence of the software; ii) cost of software's acquisition.	Models that use available online software (such as Excel) occupy the most favourable position. Models that require the application of expensive software adopted in this study appear in the bottom of the hierarchical scale adopted.
P4	Concerning the interpretability of results and usefulness of the information produced, two parameters are considered: i) readability of the output and ease of use provided by the mathematical equation models for a user unfamiliar with statistical models; ii) richness of the information obtained by the models and its usefulness for service life prediction.	Deterministic and artificial intelligence based methods lead to an average estimated value. On the other hand, stochastic models provide probabilistic information, with data concerning the risks associated to the degradation process (producing a richer information).
U1	The number and subjectivity of the variables included in the models are analysed in this criterion. Concerning the subjectivity associated with the variables, the following criteria are adopted: i) age is a parameter that is easily quantifiable; ii) variables such as distance from the sea are objective parameters (easy to quantify); iii) variables such as exposure to damp are more subjective and are more difficult to quantify.	The simple nonlinear regression and logistic regression are the most favourable models based on this criterion, since they use only one variable. The factor method is the model in the worst position, since it includes eleven variables in its definition.
U2	In this criterion, three factors are applied: i) the ratio between the average service life predicted by the model and the average service life obtained by the graphical method; ii) the deviation between the values of the estimated service life with a probability higher than 5% to be exceeded predicted by the model and observed; iii) the difference between the probability distribution that characterizes the observed values and the probability distribution associated with the observed values, assuming a normal distribution for all models.	Based on this criterion, logistic regression is the most accurate model, followed by the factorial method and nonlinear multiple regression using a Gompertz curve. The fuzzy logic model is the least accurate, resulting in an estimated average service life much higher than the values obtained through other methods, with the highest deviation between the predicted and the observed values.

The methodologies described in the previous sections are conceptually distinct and naturally lead to different results, but all of them are capable to accurately describe the degradation process of the stone claddings. The different actors in the construction sector need to decide which model to use. However, Basel and Brühl (2013) refer that a rational process of decision-making can be complex, vague and of a controversial nature, as it incorporates subjective criteria and different "points of view". In this study, a multi-criteria analysis is therefore performed taking into account the factors that should be considered by stakeholders, evaluating two points of view: the planner’s point of view (who defines the model); and the user’s perspective (who uses the model). From the planner’s point of view, four criteria are considered: P1) difficulty in learning the model; P2) time consumed in the model’s definition; P3) software used; P4) number and subjectivity of the variables included in the model. Regarding the user’s perspective, two criteria are adopted: U1) interpretability and utility of the information obtained using the models; U2) model’s accuracy.

Table 5 shows the impact profiles of the six criteria analysed for stone claddings. There are different approaches to multi-criteria models; in this study, an additive aggregation approach with compensatory rationality is adopted (Cochran and Chen, 2005). In an overall analysis, fuzzy systems are those with worst results, being the most complex model.

Table 5: Multi-criteria impact profiles evaluated for stone claddings

Model		P.1	P.2	P.3	P.4	U.1	U.2	Overall scale	Overall standardized scale
		Ease of learning	Time required to build the model	Necessary software	Variables included in the model	Utility of the results	Model’s accuracy		
Deterministic models	Simple nonlinear regression	1	1	1	1	1	0.343	5.343	0.969
	Multiple linear regression	0.75	0.998	1	0.857	1	0.878	5.483	**1.000**
	Polynomial model	0.625	0.877	0.108	0.143	1	0.576	3.329	0.520
	Gompertz curve	0.625	0.877	0.108	0.286	1	0.957	3.853	0.636
	Von Bertalanffy curve	0.625	0.877	0.108	0.286	1	0.983	3.879	0.642
	Richards curve	0.625	0.877	0.108	0.857	1	0.736	4.203	0.714
	Morgan-Mercer-Flodin curve	0.625	0.877	0.108	0.714	1	0.763	4.087	0.689
	Weibull curve	0.625	0.877	0.108	0.714	1	0.469	3.793	0.623
	Brody model	0.625	0.877	0.108	0.714	1	0.868	4.192	0.712
	Exponential model	0.625	0.877	0.108	0.714	1	0.945	4.269	0.729
	Potential model	0.625	0.877	0.108	0.714	1	0.429	3.753	0.614
Computational methods	Artificial neural networks	0.125	0	0.893	1	0.5	0.863	3.381	0.531
	Fuzzy logic model	0	0	0	1	0	0.000	1.000	**0.000**
Factorial methods	Factor method	0.875	0.752	1	0.857	1	0.991	5.475	0.998
Stochastic models	Logistic regression	0.375	0.939	0.108	1	1	1	4.422	0.763

The multiple linear regression is the model that globally presents the best results, combining an average degree of complexity with a high level of efficiency. Once the criteria to be used in a multi-criteria analysis are defined, it is possible to perform a new analysis considering the relative importance of each criterion for stakeholders. In fact, some criteria are more relevant than others, sometimes even decisive. For this, three hypothetical scenarios for the preferences of decision-makers are considered: i) scenario 1 - the decision-maker prefers the ease of the model's application, neglecting other criteria, i.e. a higher weight is assigned to the criteria related with the ease of learning, the time required to build the model and the number and subjectivity of the variables included in the model (Table 6); ii) scenario 2 - the decision-maker is essentially interested in the model's accuracy and the utility of the results (Table 7); iii) scenario 3 - the decision-maker needs to get most accurate model, in the shortest possible time (Table 8).

Table 6: Sensitivity analysis of weights assigned to scenario 1

Criteria's weight	Overall assessment of the models
λ P.1 = 2; λ P.2 = 2; λ P.3 = 1; λ P.4 = 2; λ U.1 = 1; λ U.2 = 1	1st Simple nonlinear regression; 2nd Multiple linear regression Worst performance - Fuzzy logic model
λ P.1 = 8*; λ P.2 = 2; λ P.3 = 1; λ P.4 = 2; λ U.1 = 1; λ U.2 = 1	1st Simple nonlinear regression; 2nd Factor method Worst performance - Fuzzy logic model
* Above this value, even increasing significantly the weight value λ P.1, maintaining the remaining weights unchanged, the hierarchical scale of models remains the same.	

Table 7: Sensitivity analysis of weights assigned to scenario 2

Criteria's weight	*Overall assessment of the models*
λ P.1 = 1; λ P.2 = 1; λ P.3 = 1; λ P.4 = 1; λ U.1 = 2; λ U.2 = 2	1st Factor method; 2nd Multiple linear regression Worst performance - Fuzzy logic model
λ P.1 = 1; λ P.2 = 1; λ P.3 = 1; λ P.4 = 1; λ U.1 = 5; λ U.2 = 20*	1st Factor method; 2nd Logistic regression Worst performance - Fuzzy logic model
λ P.1 = 1; λ P.2 = 1; λ P.3 = 1; λ P.4 = 1; λ U.1 = 20**; λ U.2 = 5	1st Factor method; 2nd Multiple linear regression Worst performance - Fuzzy logic model
* Above this value, even increasing significantly the weight value λU.1, maintaining the remaining weights unchanged, the hierarchical scale of models remains the same. ** Above this value, even increasing significantly the weight value λU.2, maintaining the remaining weights unchanged, the hierarchical scale of models remains the same.	

Table 8: Sensitivity analysis of weights assigned to scenario 3

Criteria's weight	Overall assessment of the models
λ P.1 = 2; λ P.2 = 2; λ P.3 = 1; λ P.4 = 1; λ U.1 = 1; λ U.2 = 2	1st Multiple linear regression; 2nd Factor method Worst performance - Fuzzy logic model
λ P.1 = 5*; λ P.2 = 5*; λ P.3 = 1; λ P.4 = 1; λ U.1 = 1; λ U.2 = 2	1st Simple nonlinear regression; 2nd Multiple linear regression Worst performance - Fuzzy logic model
λ P.1 = 2; λ P.2 = 2; λ P.3 = 1; λ P.4 = 1; λ U.1 = 1; λ U.2 = 3**	1st Factor method; 2nd Multiple linear regression Worst performance - Fuzzy logic model
* Above this value, even increasing significantly the weights values λP.1 and λP.2, maintaining the remaining weights unchanged, the hierarchical scale of models remains the same. ** Above this value, even increasing significantly the weight value λU.2, maintaining the remaining weights unchanged, the hierarchical scale of models remains the same.	

5. Discussion

The proposed service life prediction models analysed in this study present high levels of accuracy in the description of the degradation phenomena of stone claddings, according to the statistical parameters considered. In fact, all the proposed models show a MAPE lower than 10%, revealing a potentially very good predictive capacity. Additionally, the coefficients of determination (R^2) and correlation (*r*) are always greater than 0.6 and 0.8, respectively, indicating that there is a strong correlation between the observed data and the values predicted by the models. Regarding the capability of correctly classify the cases that have reached the end of its service life, it can be seen that all the models present accuracy higher than 80%, revealing a good discriminant power. The proposed models lead to an average estimated service life ranging from 66 to 90 years, for factor method and fuzzy systems, respectively. The results obtained seem realistic from a physical point of view, due to the high durability of stone claddings, and are coherent with the values present in the literature related to the service life of this type of cladding (Silva et al., 2011). When the service life of stone claddings is reached, they should be subjected to generalised rehabilitation actions in order to ensure that they are able to fulfil all the performance requirements. In fact, the knowledge of the ESL allows optimising the maintenance actions, in a rational and technically informed way, avoiding unnecessary costs (in an economic and environmental level).

For stakeholders to whom the simplicity of the model is the most relevant parameter (scenario 1), it is suggested to use an intermediate model, for example the multiple linear regression, whose modelling is extremely simple and allows encompassing the significant variables in the degradation process (unlike simple regression that only encompasses age) and factorial method (which includes more variables, although these may not be relevant to the phenomenon under analysis). In some situations, if the stakeholders want to define warranty periods and manage a large built park, it is important to obtain information regarding the degradation of the claddings in the form of a probability distribution, thereby evaluating the risk of a given decision regarding the rehabilitation of the façade; in this case, it is proposed to choose stochastic models. These methods are essential when the stakeholders intend to define with a known risk the instant after which they cannot ensure that the claddings will be able to conveniently comply with the function for which they were designed. Artificial intelligence-based models are definitely the most complex ones, whose definition is more intricate and whose results are more difficult to be interpreted. However, these models are obtained through a validation process that ensures the ability of generalization of the models. For an unfamiliar user, the accuracy of these models is not sufficiently compensatory, and it is advisable to opt for less complex models. However, in the case of a manager of a very large building stock, the high economic burden associated with the maintenance and rehabilitation of this heritage can justify the use of such tools.

6. Conclusions

Based on this study, it is not possible to unquestionably define the best model. In a global analysis, it can be concluded that simpler models consume less time and can be equally effective but analyse the problem only in one dimension, i.e. they only relate loss of performance of the stone cladding with its age. More complex models consume more time, are more complex and require software that may not be available to all and whose use may be more difficult; however, usually they are more robust and analyse various parameters that influence the degradation of stone claddings, allowing obtaining more interesting findings regarding the choice of a particular type of cladding over another depending on given environmental exposure conditions. Finally, stochastic models produce more relevant information, since they provide the probability of occurrence in order to evaluate the risk associated with the end of service life of stone claddings. Multi-criteria analysis allows a multidimensional analysis of the choice of a particular model for service life prediction. This analysis allows evaluating and comparing the different models, establishing hierarchical scales of preference. Regardless of the criteria adopted, there is always subjectivity associated with the decision-making process, since this process is conditioned by individual perceptions and actual preferences of the decision-makers. In fact, the decision-maker may not be able to define precisely the level of importance of each criterion (criteria weights), and even when he/she refers to the opinion of experts, they can assign different values to the weights of the criteria. Ultimately, it will be up to the decision-maker to choose the best model depending on the expected result, using the recommendations of this study. The selection of the best service life prediction model for a given application is extremely relevant for practical applications, such as the definition of maintenance policies for real estate managers, or the definition of warranty periods for insurance companies.

Abstract

Smart home technology (SMT) has been identified as a promising means of meeting the desire of older people to remain independent, maintaining their quality of life (QoL) while containing spiralling elderly care costs. SHT development in Hong Kong, however, as well as in many other countries, lacks sufficient reliable information on such as the needs and requirements of older people concerning technical design needs and appropriate technological solutions to address these needs. Without a clear and accurate understanding of the needs of older adults, the value of the use and implementation of SHT in support of the living of old people in Hong Kong is questionable. The aim of this paper is to present the results of an investigation into the perceptions and expectations of home-based smart technology amongst the elderly in Hong Kong. Factors influencing the decisions of elderly people to use SHT have been identified. A focus group meeting (and snowball sampling) provided the data for this study. A total of 98 participants aged between 55 and 76 participated in the study. The participants were divided into fourteen interview groups. Twelve factors influencing the use of SHT were identified from focus group discussions, which were categorised into the four groups, *operational design of devices, functions provided by devices, personal considerations,* and *external influence*. By gaining an understanding of their needs and a QoL-oriented smart home devices design model, this study provides a preliminary insight into the way SHT should be designed, adopted and implemented so as to provide a better living environment for older people in Hong Kong living independently.

Keywords: Smart home technology, Ageing-in-place, Motivating factors, Hong Kong

1. Introduction

Hong Kong is facing a sharp increase in the proportion of older people in the overall population and an increasing number of independent-living older adults. This generates significant economic and social costs, and stress placed on family, carers and the community in general. With the age-associated decline in health and functional ability, supporting older adults in line with the 'ageing-in-place' concept may require modification of their existing home settings. Smart home technology (SHT) is regarded as a potential means of meeting the desire of the elderly to remain independent, maintaining their quality of life (QoL), while containing spiralling care costs. Despite the recent Government's pilot scheme (i.e. Hong Kong Housing Society) to promote SHT in housing for the elderly, there is limited understanding of the appropriate form such SHT interventions should take. In this regard, this study aims to fill this understanding gap by identifying the factors motivating the elderly to adopt SHT. The 'third age' is the targeted potential group of ageing people in this study, because they have an out-going attitude, a relatively open mind, and better financial status for the funding of SHT. The 'third age' is that group of post-retirement people who have fewer family responsibilities, adequate resources, and good health providing freedom to seek self-fulfilment and purposeful engagement (Rubinstein, 2002; Weiss & Bass, 2002). The perception of the 'third age' group, as prospective SHT users, provides preliminary and valuable insights into SHT development planning for aging people in Hong Kong.

2. Ageing-in-place: an opportunity of SHT development in Hong Kong

The Thematic Household Survey revealed that approximately 97% of elderly respondents in Hong Kong had no intention of moving to a residential care home, and 82% prefer to remain living in their own home when the choice is available to them and their physical health and financial situation allows (Census and Statistics Department, 2009). The growing desire of older adults for 'ageing-in-place', remaining in their familiar home environment or an environment of their choice for as long as possible, reflects an optimum strategy that can reduce stress, improve their QoL, allowing continuity and self-control over important aspects of daily life. 'Ageing-in-place as the core' has been recently launched as a strategic and holistic planning policy objective for the care of elderly in Hong Kong(Labour and Welfare Bureau, 2014).

A home living environment is considered to have a strong linkage with the physical and psychological well-being of older people (Oswald et al., 2007). Past research shows that older people are likely to spend 80% of their time at home, more than other age groups (Baltes et al., 1999; Iwarsson et al., 2007). The person-environment fit model (Lawton & Nahemow, 1973) posits that older adults become increasingly reliant on their surroundings, such as their physical living environment, to offset functional decline as they continue to age (Brawley, 2001). The home environment should function to accommodate losses of physical function, enhancing the independence of older adults in daily activities and autonomy (Lawton et al., 1973). The significant advances in microprocessor-based technologies over the last decade has led to the emergence of home automation and intelligent control technologies which provide convenience, comfort, energy efficiency, security, and a better quality of home living (van Hoof & Kort, 2009; Wong, Hang, & Wang, 2005). SHT have been proposed as a possible solution assisting older people to maintain independent and safe living at home in performing the activities of daily living, predicting normal and abnormal behaviour, and alerting carers of potentially dangerous behaviour (Blaschke, Freddolino, & Mullen, 2009; World Health Organization, 2012). SHT includes a range of emergency assistance systems, security and safety features, falls prevention, sensors, and timers that aim to reduce falls, disability, stress, fear, and social isolation, and monitor the daily functioning of the elderly at home (Barlow & Venables, 2004). For example, real-time monitoring and detection of accidental falls or slipping amongst elderly people from standing, chairs, or beds (Yu, 2008) would enable first-aid by carers, families, and paramedics as soon as possible (Abbate et al., 2012). Detection of unauthorised intrusion will maintain home security (Gaßner & Conrad, 2010; Lehmann, Giacini, & Davis, 2013). Arguably, a home setting equipped with SHT should reduce stress and optimise QoL: for example, by improving functional capacity; monitoring health status, enhancing psychological well-being, increasing social support, improving morale, enhancing independence, and allowing for coping and adjustment. SHT can also help relieve the burden on carers and social support services (Blaschke et al., 2009; Demiris & Hensel, 2008).

3. Research Method

A focus group was used to gather collective thoughts and insights into the use of SHT by the senior citizens in Hong Kong. Those collective views of the research participants emerged from evaluation of their informal conversations and debates (Kitzinger, 1994; Liamputtong, 2011). Those collective views of SHT consolidate the factors identified during the conservations of this study. This research study adopted snowball sampling to expand the recruitment of the participants. Subject recruitment information was sent in two ways. Firstly, the project information and subject recruitment details were sent to members of *The Institute of Active Ageing* (IAA) of the Hong Kong Polytechnic University with the institute’s support. *The Institute of Active Ageing* is a non-profit university-driven organisation that promotes active ageing to third age people by organising a wide range of programmes and activities. Secondly, subject recruitment posters were placed around a university campus, which is located at the city centre with high accessibility. The snowball effect started from these two spreads. Most of the participants were referred by the attending participants. A total of 98 participants aged between 55 and 76 recruits and took part in the group interviews. The participants expressed their interests in the SHT topic when they signed up for the group interviews. The participants were arranged into 14 groups of size between 6 to 9 participants. Ten SHT devices were presented to the participants by short video clips. These ten SHT devices and applications were classified into living environment control, safety, health monitoring, and social communication categories (Table 1). Semi-structured questions were asked to encourage discussions on their reasons, preference, acceptance, motivation, and suggestions for using SHT.

Table 1: Categories of Demonstrated SHT Devices and Applications

Categories	SHT Devices and (Source of Video Clips)
Living Environment Control	Environmental Control System (LSCM R&D Centre, 2015)
	Energy Management System – Smart Meters (Hkbnnewson, 2012)
Safety	Cooking Safety Control (Amano Connect, 2015)
	Infrared Environment Monitoring System (LSCM R&D Centre, 2015)
	Home-stay Wellness Sensing System (LSCM R&D Centre, 2015)
	Emergency Alarm (Senior Citizen Home Safety Association, 2000)
Health Monitoring	Cardiovascular Monitoring Device (LSCM R&D Centre, 2015)
	Non-Contract Electro-Cardiogram Monitoring Bedsheet (Centre for Innovation and Technology, 2010)
Social Communication	Smart Communication Board (LSCM R&D Centre, 2015)
	Video Conferencing (CFSC, 2014)

4. Findings: Factors influencing the adoption of SHT

System support and management of devices is considered an important factor underlying the successful adoption of SHT. SHT devices and applications are usually composed of electronic components, computer programmes, and communications networks. The elderly frequently express concern about the possibility of instability or malfunctioning of SHT devices and applications due to poor system performance and electricity supply. A number of participants asked '*What I can do if the device is out of order?*' after most of the video demonstrations and '*What will happen if the electricity supply is cut?*' after demonstration of a home environment control system. The respondents further explained that they did care about support for those SHT devices and the quality of support provided by the management when there are problems. The type of supports of concern included provision of instruction, on-site service, and the response rate and time to each inquiry. Apart from system support, management of the system connecting SHT devices to the off-site systems, such as the emergency alarm and the infrared environmental monitoring system, have been considered. For example, participants are worried about whether there is a response from the operator if they press the emergency button. Regarding some monitoring systems, the participants worry whether the staff in the off-site centres, actually notice the emergency condition even though the system has alerted them. A group of participators who care about personal privacy when their living environment is connected to an off-site system and personal data is stored. This implies there are issues of trust to consider and overcome.

The maintenance of devices is another concern raised frequently by elderly participants in group discussions. Corresponding to the last factor, this concern also emerges from their perceptions of using electronic devices. Most of the participants were concerned about the need to spend a lot on the maintenance, repair, and warranty of installed SHT devices. For example, two of the most raised questions after demonstrations, are '*Is it difficult to maintain the device in daily use?*' and

‘*Is it difficult to find someone to repair the device if it is damaged?*’. Those questions indicate that participants are concerned about the robustness and reliability of SHT systems. Therefore, an all-round warranty service is preferred by the respondents to maintain the devices.

In line with the concerns mentioned above, *operational design of devices* is another crucial factor if SHT is to be used by the third age participants. In term of design, the participants prefer SHT devices to be safe, effective for ageing people’s daily activities and safety, and suitable for the Hong Kong home environment. The participants also expressed their concern for contingency design. For example, a number of participants asked ‘*Can I operate the home appliances manually without electronic supply?*’ after a video demonstration of a home environmental control system. This implies that the basic operations and functions of home appliances should not be affected when SHT devices have problems. It was agreed that these requirements related to the design of devices were applicable for all SHT devices in general. For those SHT devices that interact with ageing people, such as the smart communication board, the participants are concerned that the devices must be user-friendly and easy to learn how to use.

The *increasing popularity and level of usage and penetration of smart devices* in society is another factor that influences the decision of whether to adopt individual SHT devices. Obviously, this factor is influenced by the reputation of particular devices. The participants expressed the view that if a SHT device has high usage and penetration rates into ageing people networks and society, they would be more willing to use it. They believe that high rates of usage and penetration of a particular device are correlated with a better support and reasonable device costs. Most participants have a good understanding of the emergency alarm services (EAS) provided in Hong Kong, which reflects its high penetration rate in society. Correspondingly, emergency alarms and associate services were found as the most well-known devices during group interviews. This indicates that higher usage and penetration rates of a particular SHT device influence the willingness of people to use them.

The participants were aware that their health and physical functions would get worse as they age. The participants expressed their willingness to use SHT devices if the devices would make housework easier. The third age people worried about heavy daily activities/tasks in the future, such as cleaning windows and hanging out clothes. As Hong Kong is a Chinese culture society, 63% of elderly citizens live with family members (Census and Statistics Department, 2009). Elderly people usually take over the family housework. Some participants stated that they would rather keep on helping their families with housework instead of receiving help.

Individual needs on SHT was another issue highlighted by the third age participants to show their willingness to use SHT. The participants argued that this important factor influence final decisions on the use of a particular SHT device. As the living space per person in Hong Kong is tight and the living cost is high (Economist Intelligence Unit, 2015; Ho, 2015), the third age people are likely to install handy SHT devices which suits their individual needs, such as health and physical conditions. Participants were concerned as to whether the particular device could reduce body disorders and help to perform some daily tasks due to body limitations. In the group discussions, the participants were frequently asked in what circumstances would they use a particular SHT device.

Enhancing home safety is considered a constituent of QoL for elderly people (Cardea & Tynan, 1987; Lin et al., 2007). The participants stated that home safety is a fundamental and essential purpose of a SHT installation. The participants stated that they would consider installing and using i) infrared environment monitoring systems, ii) home-stay wellness sensing systems, and iii) emergency alarms when health and physical condition were deteriorating. Despite the fact that many participants do not intent to install these SHT devices now, they are highly likely to install them when there is a need to enhance home safety. In terms of home safety, the significance of a cooking safety control system was highlighted in some group discussions. A number of participants had experienced the case of stove left on in their home. Avoiding fire incidents in the kitchen is one of their priorities in terms of home safety.

Health is a dimension of QoL for elderly people (Bowling et al., 2013; Farquhar, 1995; Gabriel & Bowling, 2004). The home safety function provided by SHT devices helps in emergency. SHT devices designed for health monitoring, aim at recording and analysing the health conditions of ageing people in order to reduce the number of emergency situations. The discussions of health monitoring devices is now seen as an issue of public health. A number of participants argued that a long-term health-monitoring programme assisted by SHT devices is a solution, also strengthening the awareness of health by the public. They stated that the installation of health monitoring devices at home should not only be beneficial to themselves, but also to their family. They agreed that health monitoring SHT devices were important, especially for long-term health issues of the society.

The cost of SHT devices is considered another factor of significance in determining the willingness to adopt SHT devices by third age participants. The participants expressed concern about spending due to a low or zero income after retirement. They tend to save money for medical expenses, manage their budget well during life after retirement. Their consideration includes the costs of devices, costs of maintenance, and costs of management, which aligns with their concerns about the maintenance of devices, (Point 4.2) above. In addition, *the level of support from Government* on SHT adoption was raised in group discussions. The participants agreed that SHT is a good idea to encourage ageing-in-place in Hong Kong. In this regard, the participants thought that initiatives by government would be an ideal way to promote the SHT concept. According to participants' comments, potential governmental efforts could be classified into three types. First, direct financial support from the government, such as subsidies, is suggested and highlighted by the participants as necessary for promoting the SHT concept among the elderly in Hong Kong. The participants would be happy to try SHT if there is a supporting government scheme. Second, support offered to groups and organisations concerned with SHT, including research and development, manufacturers, and contractors, is a way to strengthen the functions of SHT devices. Third, the participants suggested adoption of a wider pilot scheme for SHT devices in new senior housing, to help speed up promotion of SHT to the public.

In group discussions, the importance of *communication with different parties* and *maintaining social life* were discussed and highlighted after a video of a smart communication board and video conferencing devices had been demonstrated. Sustaining communication with different parties was raised by participants in connection with QoL in social relationships (Bowling et al., 2013; Farquhar, 1995; Gabriel et al., 2004). The participants commented that communication devices and applications, such as the smart phone and desktop computer equipped for instant chatting and video call applications, are commonly used by the third age elderly nowadays. They agreed that technology helps them to maintain social connections with family members, friends, and neighbours and is crucial to their lives. They also expect SHT devices to help maintain communication with the external environment using advanced and SHT high-tech devices, for example, video conferencing video functions integrated with other home appliances.

The factors identified in this study can be categorised into four types (Table 2). The findings indicate that ageing people take operational issues into account when thinking of using SHT devices. The identified factors relate to ***operational issues of SHT*** include system support and management of devices, maintenance of devices, and operational design of devices. The participants particularly raised some ***functional SHT considerations***. Those include support of housework, enhancing home safety, health monitoring, and maintaining communication with the external environment. Ageing people expect SHT to provide housework support, home safety, health monitoring, and communications. In addition, the individual needs and financial considerations indicate ***the individual concern*** when thinking of using and installing SHT. The identified factors indicate that ***external issues*** also affect the use of SHT by ageing people. These factors include levels of usage and penetration of devices, government support, and family support. These four types of factor encompass a wide range of considerations by ageing people when using SHT.

Table 2: Four categories of found factors

Categories	**Found Factors**
Operational Issues of SHT	System support and management of devices
	Maintenance of devices
	Operational design of devices
Functional Consideration on SHT	Support to housework
	Enhancing home safety
	Health monitoring
	Maintaining communication with external environment
Individual Concern	Individual’s needs
	Financial considerations
External Issues	Level of usage and penetration of devices
	Government support
	Family support

5. Conclusions and Further Study

This study has identified factors that motivate the adoption of SHT, which meets the ageing-in-place desires of the local older adults. This paper provides preliminary insights into the potential for SHT in Hong Kong, and makes four proposals for promoting aging-in-place through SHT, as follows: i) enhance the operational design of SHT devices; ii) match the needs of the elderly with the functionality of SHT, iii) improve support for SHT adoption, and iv) understand the needs of ageing people in relation to SHT. In the next phase, the data collected will be further analysed so as to understand the interrelationships between these factors using the interpretive structural modelling (ISM) approach. With the appropriate technological intervention, this generates a 'win-win' situation for the elderly, carers, the community and the government in the long run, by enhancing the independence of older people and reducing the burden and distress of the carers, releasing government institutional healthcare funds and older person's time for more productive activities in support of the national economy, leading to a more cost-effective and less-dependent need for public-sector service provision.

Offsite Manufacturing in Nigeria: Feasibility Research and Future Directions

Shaba James Kolo, Farzad Pour Rahimian and Jack Steven Goulding

School of Engineering, University of Central Lancashire, Preston, UK.

Email: sjkolo@uclan.ac.uk

Abstract

Nigeria is facing a deficit of 17 million houses due to a myriad of issues. This paper reports on the findings of a feasibility study which investigated Nigerian stakeholders' perceptions on the needs, promises and barriers of adopting Offsite Manufactured Construction (OSM) in Nigeria, in order to address this challenge. In-depth interviews were conducted with domain experts directly involved in housing delivery, the data of which was analysed using thematic analysis, powered by Nvivo software. Results showed that although OSM could improve housing delivery efforts in Nigeria, any such initiatives to support this were perceived to be considerably low. As such, this study concluded that there is a need for high-level awareness, greater collaboration, investment in training and education, and endorsement/encouragement from the Government. This study presents additional understanding of OSM in Nigeria based on expert opinion, the results of which were used in the development of a framework for the effective adoption of OSM in Nigeria. It is proffered that adopting OSM can help support housing delivery efforts in Nigeria, and may also leverage wider benefits to the construction industry and associated supply chain.

Keywords: Offsite Manufacturing, Housing Delivery, Stakeholders, Nigeria

1. Introduction

Nigeria is currently facing a significant and progressive housing deficit. Whilst it could be argued that this is similar to many other rapidly developing countries, there are some unique contextual facts that need to be noted. For example, it has a population of 177 million, with an annual growth rate of about 2.5% (PRB, 2014). It also needs about 17 million new houses in the short term (Okonjo-Iweala, 2014). Thus, in order to address these issues, several mitigation efforts have been deployed by the local industry, including: promoting locally manufactured building materials as a means of improving housing delivery (Olayiwola & Adedokun, 2014); directing the industry towards better implementation of the Nigeria National Housing Policy (Makinde, 2014); and seeking possibilities of introducing better mortgage systems in Nigeria

(Olayiwola & Adedokun, 2014). Despite the success of some of these innovative attempts to address the problems affecting housing delivery in Nigeria, a wide margin still exists between housing demand and supply (Ibimilua & Ibitoye, 2015). Acknowledging this, it has been argued in seminal literature that this is mainly due to the inherent problems of the exiting conventional housing delivery systems in Nigeria and concomitant challenges, such as time and cost overruns, skills shortage, inadequate quality, and labour intensive activities (Femi & Khan, 2014; Makinde, 2014). As such, Dada (2013) suggested that a paradigm shift from the conventional construction approach to a more innovative housing production processes was vital in the context of Nigeria.

This kind of radical change in housing delivery methods was also advocated in several other countries, e.g. in the UK, USA, Australia and South Africa. Several Government reports have also noted that collaborative working and integrated project delivery must be promoted in order to make a 'revolution' in construction projects. To leverage these, literature has proffered the adoption of Modern Methods of Construction (MMC) and Offsite Manufactured Construction (OSM) as viable delivery mechanisms for both developed and developing countries (Gibb & Pendlebury, 2006; Goulding et al., 2014; Mullens & Arif, 2006; Nadim & Goulding, 2010; Taylor, 2009). In this respect, the primary role of OSM here is to move some of the effort and risk prone construction site activities into a 'controlled environment' typically associated with a manufacturing or factory facility (Arif et al., 2012). This controlled environment and application of OSM offers several benefits, particularly: a higher speed of construction, improved quality of the finished product, lower costs, and lower labour requirements on-site (Mullens & Arif, 2006). These achievements are sustained and significant; and it is therefore proffered here, that such offerings may act as a platform for addressing the specific housing problems of Nigeria (discussed above).

Despite these potential benefits, OSM only has a negligible share of the housing market in Nigeria (Kolo *et al.*, 2014). Taylor (2009) asserted that this failure in many countries could be due to inaccurate public assumptions regarding offsite. This study therefore posits that, if offsite production and manufacturing are to make a positive contribution to the Nigerian construction industry, there is a need to identify the causal issues associated with its uptake and adoption. This undertaking would need to encompass several areas, not least, market drivers and dynamics, culture, societal issues, and existing economic business model

2. Background of the Study

Statistics are not promising at all about housing delivery in Nigeria, where only 10% of Nigerians can currently afford to either purchase or build their desired quality houses, compared to those for other countries 72% in USA, 78% in UK, 60% in China, 54% in Korea and 92% in Singapore (Ayedun & Oluwatobi, 2011). Olayiwola and Adedokun (2014) complained that the housing situation in Nigeria is far from being satisfactory, taking into account the high rates of urbanisation and population growth in this country. Makinde (2014) asserted that there was no perspective of improvement in near future; if the country decides to continue to rely on its conventional housing delivery systems, which are deficient in terms of quantity and quality of housing units delivered. These problems tend to have a cascading effect that results in the other housing problems, such as unstable businesses, shortage of skills and materials, inadequate infrastructure, lack of innovation and unfair distribution of resources.

3. Offsite Manufacturing and the Opportunity for Its Adoption in Nigeria

Offsite manufacturing falls under the broad umbrella of Modern Methods of Construction (MMC) (Nadim & Goulding, 2010) and, there are several acronyms associated with OSM. OSM can be defined as set of processes that incorporates prefabrication and pre-assembly to produce units and or modules that are then transported to site and positioned to form a permanent work (Gibb, 1999). From a system point of view, Gibb and Pendlebury (2006) defined OSM as a range of applications which involve moving operations that are traditionally completed onsite to a manufacturing environment. This transformation improves the quality, customer satisfaction, efficiency, predictability of delivery timescale and sustainability of a project (Nadim & Goulding, 2010). It has been widely advocated that several benefits are obtainable from the use/adoption of OSM. The following paragraphs provide a categorised summary of these benefits in accordance to main themes of housing challenges in Nigeria, which were discussed in the previous section.

Ajayi *et al.* (2008) presented shocking statistics about waste generation in Nigerian construction projects where more than one-ton per day waste is generated in more than 75 per cent of conventional building sites. They also argued that most wastes are generated from demolition works on site and material handling. According to a report by Waste and Resources Action Programme (WRAP, 2007) within the context of UK, 40 per cent of all council waste come from construction projects. OSM has been successful in reducing waste generation of typical construction projects by 70% to 90%. It has also been advocated that it is much easier to gather and recycle waste generated from OSM than those for conventional construction projects (WRAP, 2007).

Gibb and Pendlebury (2006) asserted that “time is a big-plus for offsite”. Similar to other countries, construction projects in Nigeria often delay due to some regular issues, such as material shortage, skills shortage and bad weather conditions (Mansfield *et al.*, 1994). With OSM, these issues are inherently addressed, since most of the building components are manufactured in factories and transported to site for speedy assembly at very predicted times with limited workforce (as per discussed with very much detail in: Arif *et al.*, 2012; Gibb & Isack, 2003; Taylor, 2009). (See Figure 1).

Despite the higher initial cost of OSM projects (NAO, 2005), savings from OSM can be achieved in the areas of cost certainty and reduced risk, reduced running and maintenance costs, reduced preliminaries and site overhead, and reduced construction time (Gibb & Pendlebury, 2006). WRAP (2007) also identified that, savings can be achieved by using OSM as a result of reduction in waste of building materials especially bricks. In Nigeria were sandcrete blocks are predominantly used, incorporating OSM will go a long way in reducing waste on site and this will in turn augment for the high cost of construction when using OSM.

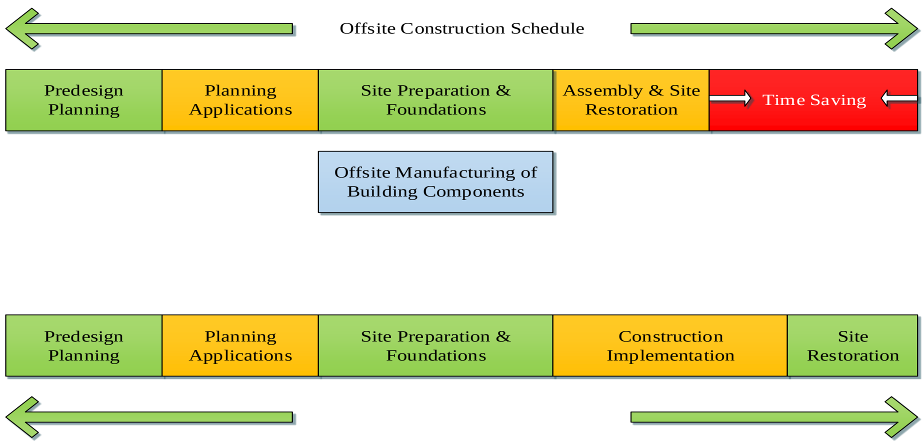

Figure 1: Comparison between OSM Schedule and Conventional Construction Schedule; Adapted from *MBI (2010)*

NAO (2005) advocated that OSM meets the three quality requirements of durability, whole life cost and performance. It was ascertained that achieving greater quality was a major benefit and a key driver to the adoption of OSM in various contexts of different countries such as India (Arif *et al.*, 2012) and UK (Gibb & Isack, 2003). Gibb and Isack (2003) linked this superiority in the production quality and output consistency to the controlled factory environment in OSM as opposed to the uncertain conditions of a conventional construction site.

Despite all benefits, seminal literature highlights myriad of barriers hindering the uptake of OSM (e.g., Arif *et al.*, 2012; Goulding *et al.*, 2014). It was crucial for this research to identify these barriers through reviewing literature and investigate their likelihood within the context of Nigeria based on evidence from primary data.

Initial cost of products has often been considered as the main barrier to the uptake of OSM in many countries including Nigeria. Scofield *et al.* (2009) also identified manufacturing capacity as another barrier to the uptake of OSM. Countries in which OSM usage has already been established, (e.g. UK, US, Japan and Nordic countries) have a robust supply chain including good number of factories to support OSM market. In a country like Nigeria, there are only few factories involved in the manufacturing of OSM components. This can certainly hinder update of this industry in the future. Another barrier hindering the uptake of OSM is the negative public and stakeholders' perceptions towards OSM. Arif *et al.* (2012) argued that one reason for this is that prefabricated housing was used during periods of high demand (e.g. post-world wars), resulting in mostly low quality shelters. Although this has changed in many countries, Opara (2011) confirmed that similar negative perception still is a real barrier in Nigeria.

Another major barrier for adopting OSM in many countries is lack of suitable building codes and standards (Goulding *et al.*, 2014). This is a problem in Nigeria also where there are no official codes and standards to guide the use of OSM. Shortage of skilled workers and labour specific for OSM has also been a regular issue for OSM adoption (Goulding *et al.*, 2014). This problem is even magnified in countries like Nigeria where the OSM industry is too small, so that there is too much reliance on expatriate skills (Opara, 2011).

4. Research Methodology

This study focuses explicitly on the barriers of adoption of OSM in Nigeria. As such, a narrow-bounded literature review lens was used to identify the main problems affecting housing delivery in Nigeria, cognisant of the globally recognised capabilities of OSM in addressing these issues, barriers and subsequent transformation from conventional construction to OSM. The results of the conducted literature developed the theoretical framework and identified main constructs, factors and variables of this study. It was also essential to get affirmation for the developed theories through checking them against tacit knowledge of stakeholders involved in the Nigerian housing industry. Since not much research have been conducted in the past to investigate issues related to OSM adoption in the context of Nigeria, a qualitative research approach was adopted, using in-depth interviews as the instrument for data collection, to engage profoundly with actual stakeholders, get their views and opinions, and capture deeper knowledge about the nature of these issues. Due to the nature of qualitative study, very high-level experts from various sectors of the Nigerian housing industry were selected and invited as the participants for the in-depth interviews.

The study followed Gu and London (2010) in shaping the main constructs of the study and interview questions around the three main dimensions of OSM, i.e. people, process and technology. Cost was also included as the fourth construct, since it has been identified as a major player in housing delivery by various studies. The interview questions were divided into three main categories in accordance with the main aim of this study, specifically: 1) The main problems of housing in Nigeria, 2) The potential capabilities of OSM, which can leverage housing delivery in Nigeria, and 3) The probable barriers to OSM adoption in Nigeria.

In order to engagement effectively with the respondents, face-to-face interview was selected as the method of conducting the interviews and about 30 minutes was allocated for each interview. Interview questions were also tailored to the expertise of each participant to assure maximum productivity of meetings. Reaching theoretical saturation (Kumar & Phrommathed, 2005) was the main strategy for determining sample size of each set of interviews; i.e., the study continued the interviews with new participants from each group, until the point whereby no new data was received from the new respondents. Data gathered for the interviews were audio recorded with the permission of the interviewees to ensure all necessary information were captured for proper analysis of the data.

Total of 26 experts were approached for interview based on the roles they play in the housing delivery value chain of Nigeria. All data gathered from 26 interviews was transcribed and analysed using the QSR - NVivo Data Analysis Software (V10.0.638). In order to systematically investigate the core issues of housing delivery in Nigeria and the potentials of OSM to address these issues, this study adopted thematic content analysis.

5. Results and Discussions

5.1. The Problems of Housing Delivery in Nigeria

From an exploratory analysis of the interview results, it was obvious that despite the various mitigation attempts, the problem of housing deficit in Nigeria continues to remain. It was reaffirmed by results of this study that a large housing deficit still exists in Nigeria and currently, there is no promising prospect for improvement. It was strongly pointed by many interviewees that this problem is likely to be even more serious than what has been officially reported, and nothing significant is being done to tackle this issue. The following paragraphs present the details of the problems of effective housing delivery in Nigeria.

Respondents of this study identified *financial issues* as a major hindrance to effective housing delivery in Nigeria. High cost of construction in Nigeria was brought into conversation by many of interviewees and this concurs with results of a previous research conducted by Odunjo (2013) highlighting this issue. The results of the interviews point out several factors which account for the high cost of housing in Nigeria. One of the most crucial issues highlighted here was overheads imposed due to lack of proper infrastructure. Another subset of cost is the cost of getting title documents in Nigeria which is usually very high and this also impacts on the overall building cost. Other sub categories indicted as major factors contributing to high cost of construction in Nigeria included importation of building materials and poor earning power.

In terms of *construction sector related issues*, this study identified various factors which have negative impact on housing delivery in Nigeria. Lack of construction standards and poor professional ethics were identified as two main codes under construction sector related issues. One of the interviewees argued that *"so many people tend to cut corners with regards to building materials…"*. This concurs with the findings of an earlier study by Solaja (2015) which complained about poor ethics within the Nigerian construction industry at every level. Similarly, it also reaffirms the findings of Oseghale *et al.* (2015) who argued that use of unqualified professionals, lack of maintenance culture, poor quality materials and inadequate fund are some of the major causes of building failure in Nigeria. Similar to every other context (Kamara *et al.*, 2004), the issue of the fragmented nature of the construction industry was also identified as a major contributor to hindrance of housing delivery in Nigeria. Other sub categories identified under this theme by the interviewees were reluctance to innovate and lack of investment and research.

The last theme identified in this section was *Government related issues*. This theme referred to issues concerning the Government role in supporting or hindering housing delivery at all levels. Importance of the Government to assure that everyone has access to at least a quality shelter as basic need of mankind (Olayiwola *et al.*, 2005) was highlighted by many of respondents. The respondents complained that the Government has not been successful in providing this in Nigeria. Other codes highlighted under this theme were inflation of contract prices, poor Government policies and lack of control on corrupt practices. The results of the interviews conducted revealed that these three areas tend to significantly affect housing delivery in Nigeria.

It was also argued by the interviewees that Nigeria needs a robust mortgage system to assure continuity of supply and demand within the construction industry. It was also brought to attention through the interviews that the issue of poverty affects the acquisition of housing in Nigeria and this is further compounded by the poor Government policies concerning housing and mortgage.

5.2. Barriers to the Use of Offsite Manufacturing in Nigeria

With regards to contribution of OSM to the Nigerian construction industry, many interviewees that participated in this study argued that OSM is almost of non-existence in the context of Nigeria. Similarly, they also asserted that OSM has not been accepted formally or even informally in this country. However, some interviewees mentioned that OSM had an acceptable share of the construction market of Nigeria during the 1970s and 1980s, and then it gradually disappeared due to the minor demand for housing at that time, and the fact that it was only the Government demanding for prefabricated houses during that period. Nevertheless, the stakeholders interviewed in this study admitted that prefabrication is vastly used in some civil engineering projects carried out by large construction firms in Nigeria, but this has nothing to do with the housing sector, which heavily relies on the conventional bricks and blocks construction methods. Despite its missing role, this study argues that due to the typical challenges that the Nigerian housing industry currently faces, it would be paramount for this industry to adopt OSM, which is already capable of addressing many of these issues (Arif, 2012; PrefabNZ Incorporated, 2013). In the meantime, for OSM to be adopted in Nigeria there was a need to identify the barriers that can hinder its adoption. This study identified three core themes (Pan *et al.*, 2004) with respect to barriers to OSM adoption, namely "human barriers", "technical barriers" and "industrial barriers".

Human barriers covers barriers that are concerned with the stakeholders involved in the delivery of housing in Nigeria as well as the end-users. Several studies identified negative perception about OSM as a major barrier for its adoption (e.g. Arif *et al.*, 2012; Pan *et al.*, 2004; PrefabNZ Incorporated, 2013). This was also echoed by the respondents of this study who argued that people in Nigeria have a negative perception about OSM components and think they are not so strong. Based on the results of this study, other major codes identified under the category of human barriers to OSM adoption in Nigeria include: maintenance difficulties, client's resistance, cultural issues and design flexibility.

Technical barriers refer to the barriers that hinder the construction process and the procedure that end up with the final product, i.e. a house. The main categories identified under this theme were lack of necessary infrastructure, lack of machinery, logistics and technical expertise. In terms of Infrastructure development, it was discussed by many respondents that Nigeria needs much better roads, transportation system, and power grid in order to be able to adopt OSM. These results resonate with the results of a similar study by Arif *et al.* (2012), which identified infrastructure as a major challenge to OSM adoption in a similar context such as India.

This study identified the *industrial barriers* as high cost of establishing factories, importation of materials, need for expatriate workers and limitation of existing OSM factories as major barriers to OSM adoption in Nigeria. Although cost has been identified as a major barrier, many of the interviewees argued that some of the initial costs could be offset through the areas such as cost certainty and reduced risk, less overall life cycle costs due to better quality of products, reduced preliminaries and site overhead, reduced construction time. This is very aligned with the findings of Gibb and Pendlebury (2006). Some interviewees also advocated that despite being capital intensive, investment in OSM could be very beneficial for Nigeria anyway, since the country would reap the benefits of OSM in the long-term.

6 Conclusion

Research findings indicate that whilst there is still a very large housing deficit in Nigeria, there are currently no significant measures implemented to address this challenge. However, OSM has been proffered as a potential solution, particularly though its ability to meet volumetric delivery patterns with reduced costs and improved quality thresholds. That being said, contextual conditions need to be assessed before this can be considered a viable solution. In doing so, several barriers to OSM adoption were presented and discussed. Based on this, low-impact construction methods (such as OSM) were considered viable methods for improving sustainability and particularly, feasible solutions for improving the housing deficit. This study presented a series of underpinning steps based on the view of various stakeholders on the issues regarding these housing challenges, and the possibility of OSM adoption. Whilst these context-specific OSM barriers highlighted the barriers, this is just a start. There is an exigent need to investigate these issues further, as it is important to proffer bespoke solutions to this environment e.g. infrastructure and local suitable materials for OSM. For this to be achieved, the experience garnered in other contexts need to evaluated regarding their suitability.

In pursuance of this, the ultimate goal of this research will be to develop a roadmap that will facilitate the effective adoption of OSM in Nigeria. This paper presented a series of underpinning steps based on the views of various stakeholders on the barriers to OSM adoption in Nigeria. Whilst OSM barriers have been highlighted within the Nigerian context, there is an exigent need to investigate these issues further, as it is important to proffer solutions to this environment e.g. infrastructure and local suitable materials for OSM. For this to be achieved, it is imperative that these issues are studied further, cognisant of experience garnered in other contexts and this will be useful in developing a suitable roadmap for the successful adoption of OSM in Nigeria.

Abstract

Hong Kong is an international metropolis, which is suffering from a chronic lack of land resources, housing supply, and the effects of high density urban development. Although a number of studies have been conducted to explore the feasibility of increasing development intensity by assessing environmental impacts, infrastructure capacity and public consultation, these reviews and assessments were implemented using 2D Geographical Information System. However, most people cannot visualize the impact of relaxed plot ratio/building height (PR/BH) restrictions from a 2D drawing, as the spatial distribution of land unit in the real world is 3D. This study aimed to measure the effects of minor relaxation of maximum PR/BH restrictions of 21 sites in Kai Tak Development Area from a sustainability perspective using 3D modelling and spatial analyses, including urban skyline, visual effect of mountain ridgeline, shadow and solar exposure, wind ventilation, and air temperature. Different scenarios with various PR/BH restrictions for the 21 target sites were generated and compared. With Hong Kong as the case study area, results indicated that people could obtain a more holistic view and be able to make more effective and informed decisions based on 3D modelling and spatial analysis. Considering the minor effects or slight changes during the various analyses, Scenario 4 is the recommended reasonable scale to relax the maximum PR/BH restriction for the 21 target sites. The proposed method can also be applied in urban renewal for other densely populated cities.

Keywords: 3D modelling, 3D spatial analysis, Micro-climate simulation, Planning decision, High-density city

1 Introduction

Similar to many global cities, Hong Kong (HK) is suffering from a chronic lack of land resources, housing supply, and the effects of high-density urban development. Over 7,000,000 people live in this tiny place with an area of only 1104 km^2. Even worse, almost 75% of this land is covered with mountains and country parks, which are unsuitable for urban development/redevelopment. Shen et al. (2009) explained that land use is crucial for both current and future sustainable urban development. To achieve sustainable development in HK, the Government has made every effort to increase land supply by adopting a multi-pronged approach in the short, medium, and long term. To increase land supply within a short time frame, increasing development intensity of built-up area by minor relaxation of the PR/BH height restrictions is commonly employed.

In HK, development intensity is mainly controlled based on lease conditions, statutory outline zoning plan (OZP), and the Building Planning Regulations, which aim to impose restrictions on site coverage and PR/BH of individual land lots. As a statutory organization, the Town Planning Board (TPB) is responsible for the approval of OZP and any subsequent amendments. There have been rising concerns in recent years that possible undesirable effects of high-density development may be caused by further relaxation of density control in urban areas. Therefore, TPB needs to consider these applications while ensuring that the proposed changes not only have the satisfactory and acceptable environmental impacts on surrounding areas but also will be in line with the HK Planning Standards Guidelines. The employment of 3D modelling and Geographical Information System (GIS) analysis technology meets this demand, which can facilitate a more interactive debate on urban density and informed planning decisions toward better provision of urban space.

As part of the Government's effort to increase housing and office supply, the Civil Engineering and Development Department (CEDD) proposed a minor relaxation of the maximum PR/BH restrictions for three study areas marked in Fig. 3, including 21 sites zoned as Residential, Commercial, Mixed Use, as well as Government, Institution, or Community, on the approved Kai Tak OZP (CEDD, 2015). Although previous research findings can provide fundamental and valued resources for this study, they were conducted using 2D GIS. Given that the spatial distribution of the land unit in the real world is three-dimensional, 3D GIS can help us examine the world in true perspective and make effective decisions. Therefore, this study aimed to measure the effects of minor relaxation of the maximum PR/BH restrictions of 21 sites in the Kai Tak Development Area (KTDA) from a sustainability perspective through 3D modelling and spatial analysis technology, including urban skyline, visual impact of mountain ridgeline, shadow and solar exposure, wind ventilation, and air temperature. The results of this study can be used to develop informed strategies for other global cities facing similar issues on urban development/redevelopment.

2 Literature Review

With the rapid development of 3D GIS technology, an increasing number of researchers are using 3D GIS to assist in various decision-making processes for urban development.

Zhang et al. (2004) conducted 3D spatial analyses for urban development using 3D models, including visibility, solar panel, flood, and air pollution. Similarly, to obtain more vivid effects, Mak et al. (2005) conducted an urban skyline analysis covering HK using 3D GIS technology. Their findings indicated that 3D GIS plays an important role in implementing the urban design guidelines (UDGs) of HK, including the quantitative measurement of mountain ridgeline, the height of buildings, and urban skylines. Stevens et al. (2007) employed a novel tool named iCity, which runs in a 3D environment to assist in spatial decision making during urban planning. Alternatively, Li et al. (2004) used ArcGIS spatial analysis functions to analyse the sky view factor, which is one of the important factors affecting climate during the urban design process. Wong et al. (2011) described an original methodology applied 3D GIS to investigate the "wall effect" caused by proliferation of high-rise buildings along the coast in Kowloon, HK.

Although the abovementioned studies focused on using 3D spatial analysis technology to address certain issues encountered during urban development, few researchers have emphasized development control, such as the effect of minor relaxation of the maximum PR/BH restrictions on surrounding environments. Therefore, the present study, investigated the viability of minor relaxation of the maximum PR/BH restrictions using 3D modelling and simulation technology to provide sufficient evidence to the decision maker.

3 Research methodology

3.1 Overview of the Research

Fig. 1 presents the overall framework of this study. First, based on the available 3D spatial data and approved Kai Tak OZP, a model of the whole KTDA was generated. A number of spatial analyses from various scenarios on urban skyline, visual effect of mountain ridgeline, shadow and solar exposure, wind ventilation, and air temperature were then conducted. Besides, Digital Elevation Model (DEM) was integrated with the 3D models to conduct the spatial analysis of mountain ridgeline. The findings of the above spatial analyses were compared under four different PR/BH scenarios. Furthermore, a previous study on the Environmental Impact Assessment and carrying capacity of infrastructure was used as a reference before a conclusion was drawn.

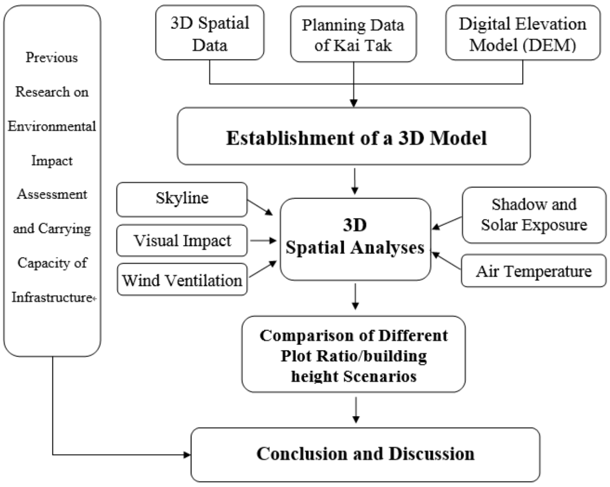

Figure 1: Framework of the study

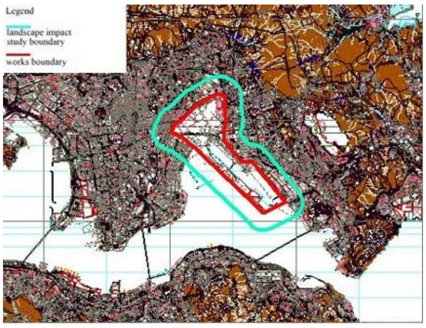
3.2 Data Collection and 3D Modelling

A case study was chosen in HK, which is an international metropolis with a high population density. The study areas were finally defined with assistance from DEM, the ridgeline of mountain, visual environment, and other related factors. Fig. 2 shows that the inner area boundary in red is the Kai Tak rebuilt planning area, whereas the outer area boundary in green represents the potential boundary of the affected adjacent region.



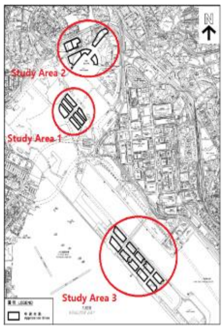


Figure 2: Selected study area *Figure 3: Target sites distributed in three study areas*

To date, only part of the 3D data for the KTDA is available from Lands Department of Hong Kong. However, for areas without existing 3D data, the 3D models were generated by commercial software CityEngine according to the planning scheme. Fig. 4 shows the 3D spatial data covering the highlighted area (in pink). The creation of new buildings should refer to a number of planning regulations, including TPB (2012 & 2015) and Building Department (2012).

Four various scenarios with different PR/BH restrictions were established for our study. Scenario 1 (S1) represents the original plan, which follows the maximum PR/BH defined by KTOZP or BPRs. Scenario 2 (S2) is the approved plan proposed by CEDD. Scenarios 3 (S3) and 4 (S4) are the further increased PR/BH based on S2, which was assumed intensively in this study. In the site of 1k1 in Area 1, the plot ratio was increased by 22% (from 4.5 to 5.5) between S1 (the original plan) and S2 (already approved plan) after comparison. Similarly, the plot ratio of S3 increased by half of this growth rate (11%) to 6.1, whereas the plot ratio of S4 increased by the same growth rate of 22% to 6.7. A similar formula was applied to the calculation of building height for each scenario. Simultaneously, the same area was assumed with the height of 2.9 m for each floor. Finally, the Gross Floor Area per floor and site coverage in each scenario could be achieved. In the same way, rules for establishing scenarios of other sites were acquired.

ArcGIS and CityEngine were employed to model 3D buildings for the three study areas. ArcGIS was applied to model the footprints of buildings. Footprints were modelled in/around the three study areas according to the layout map. CityEngine helped transform 2D footprints to 3D models. Finally, all the generated 3D building models, surrounding building models, and terrain data were integrated (Fig. 5) for further 3D spatial analyses.

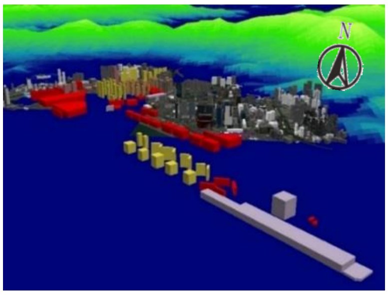

Figure 5: 3D models of the KTDA

3.3 Three-dimentional Spatial Analyses

1) Urban Skyline

Urban skyline serves as a kind of fingerprint as no two skylines are alike. For this reason, skylines are always presented to establish a city location, as well as used for city renewal (Skyline, 2015). As Fig. 8 shows, two skylines were drawn to show the profile of this study area. In particular, Skyline 1 crosses Study Areas 1 and 2, whereas Skyline 2 passes through Study Area 3. A comparison of the four different scenarios will reveal the extent in which the increased building height affects the profiles.

Figure 8: Two skylines

Figure 9: Ridgelines on Kowloon and HK Island

2) Visual Effect of Mountain Ridgeline

Ridgelines and peaks are valuable assets for HK according to UDGs, especially those located close to the city center in Kowloon and HK Island, shown in red in Fig. 9 (Planning Department and RMUM Hong Kong Limited, 2002). Therefore, protection of ridgelines is an important step and worth special attention during urban development. The long-term objective is to promote HK's image as a world-class city by enhancing the quality of our built environment from both functional and aesthetic perspectives.

There are seven vantage points around Victoria Harbour (VH) as start reference points for consideration of views to ridgelines/peaks (Fig. 10). Considering the study area location and visual factors, only three vantage points along VH in HK Island were chosen, namely, Quarry Bay Park, HK Convention and Exhibition Center, and Sun Yat Sen Memorial Park.

Figure 10: Popular vantage points

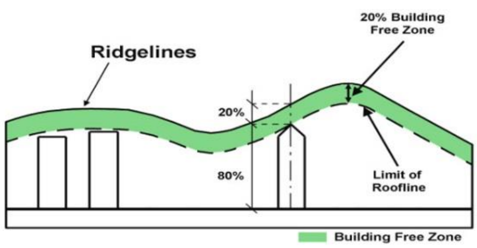

Figure 11: Building free zone

To conserve the precious ridgelines and peaks, a 20% building free zone (Fig. 11) is recommended to be maintained according to Metroplan (Hong Kong Planning Department, 1991) guidelines. Following this suggestion, a number of sampling points with 1° interval were identified along the limit of roofline for the mountain in Kowloon Island. View corridors from the three abovementioned vantage points to the limit of roofline were established to determine the effects of visibility.

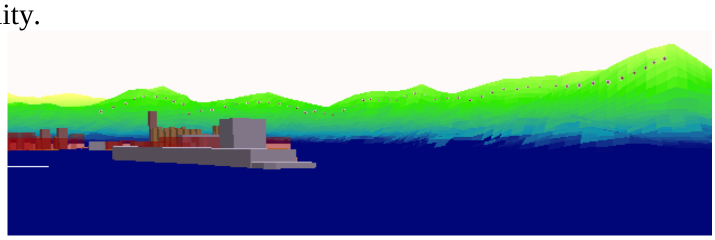

Figure 12: Sample points on the limit of roofline

3) Shadow and Solar Exposure

Sunlight is visible during the day when the sun is above the horizon of the Earth, which is a part of electromagnetic radiation emitted by the sun (Sunlight, 2015). A shadow is a region where sunlight is obstructed by an opaque object (Shadow, 2015). Generally, sun exposure hours are normally used to measure solar exposure.

In this analysis, the effects of sunlight hours and the distribution of solar exposure with the minor relaxation of PR/BH through comparison of S2 versus S3 and S2 versus S4 were investigated. With careful consideration, three analysis areas shown in Fig. 13 were determined based on solar altitude (20°) and sunlight shadow. Considering sunlight intensity and illumination time, summer was the most suitable season out of the four seasons. Finally, the average sunlight hours per day and related locations were calculated.

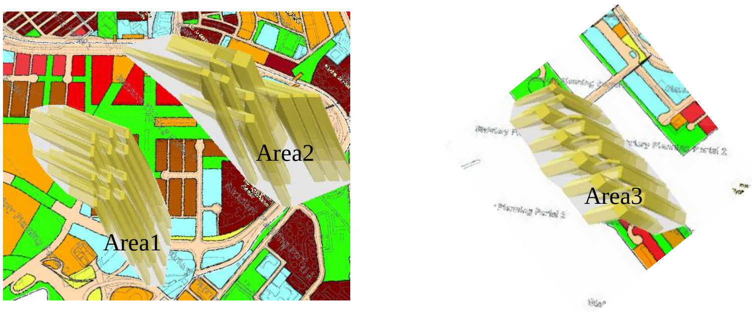

Figure 13: Three analysis areas chosen in summer

4) Wind Ventilation and Air Temperature

(i) Introduction of ENVI-met

ENVI-met is a 3D model that can simulate the microclimate of an appointed area. The simulation is based on fluid dynamics and thermodynamics, and the results consider the interaction among soil, vegetation, and the atmosphere. To simulate the microclimate using ENVI-met, a few assumptions should be considered, such as a steady temperature inside buildings and no heat storage in buildings. Therefore, the simulated result only relies on physical influence instead of anthropogenic effect. Moreover, the soil temperature and humidity in the modelling areas follow the default setting during the simulation.

(ii) 3D Modelling Regulations in ENVI-met

The model size in ENVI-met in the early stage should be determined using building footprints. To avoid the jet effect of the wind above the top of the models during the simulation, some regulations must be followed. The building height (Z) of the models in the three study areas should be twice the height of the highest building for each study area. The resolutions of all the models were the same to prevent the simulation results from being affected by different modelling settings.

(iii) Modelling of the Study Areas and Surroundings

After determining the model size, the study areas and surroundings were modelled in ENVI-met. With the aid of ArcGIS and CityEngine, the same building location, shape, and building height used in the former analyses were extracted. The building model was developed in ENVI-met by allocating height values to the grids forming the shape of the buildings. In the modelling process, only buildings were considered, and the wall properties and the roof materials of the buildings were assumed to be hollow block and concrete slab. The equidistance method was chosen for the generation of vertical grid; thus the vertical grids were of the same size apart from the bottom one. Similarly, the same four scenarios were developed for future simulation and comparison of wind ventilation and air temperature.

(iv) Configuration Setting and Simulation

To implement a simulation, configuration settings should be provided beforehand. This software requires initial weather information, including wind speed, wind direction, air temperature, relative humidity, and special humidity in 2500 m, for a particular date and time (Table 1). All the past raw weather data records were kept by the Hong Kong Observatory. Considering that significant changes in wind ventilation and air temperature appear in winter, 4 February 2014 was chosen as the testing date. The air temperature on this selected date was close to the average temperature that February.

After completing the configuration setting, the models were run for different scenario simulations. During the simulation, the calculated meteorological data, including wind speed, air temperature, humidity, and some other data such as surface temperature and soil humidity, were allocated to each grid in the ENVI-met model. The data formed an output file in the designed time interval for further analysis.

Table 1: Configuration setting in ENVI-met

Figures \ *Values*	*4 Feb 2014 (Winter)*
Start time of simulation	*7:00am*
Total simulation time (hour)	*24*
Model state saving interval (min)	*180*
Receptors state saving interval (min)	*60*
Wind speed in 10 m above ground (m/s)	*5*
Wind direction	*Southeast*
Roughness length at reference point	*0.1*
Initial atmosphere temperature (K)	*291*
Specific humidity in 2500 m (g Water/kg air)	*7*
Relative Humidity in 2m (%)	*88*

4 Experimental Results and Comparison

1) Urban Skyline

Fig. 14 shows Skyline 1 of the three study areas in different scenarios. The building heights in Areas 1 and 2 gradually increased from Scenario 1 to Scenario 4. However, the effect of increasing PR/BH on the scene of Skyline 1 was not significant. Compared with the traditional baseline photographs for landscape assessment, 3D GIS provides a more vivid and convenient way to show the city profile using skyline.

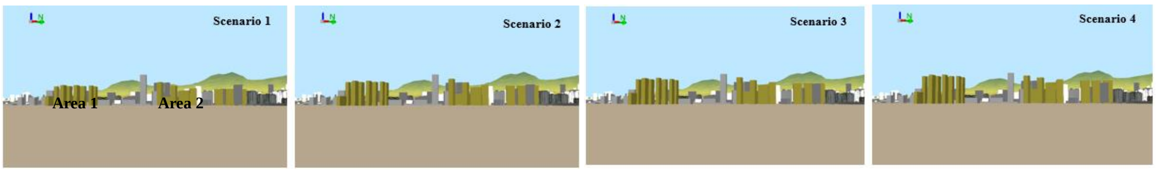

Figure 14: Scenes of Skyline 1

2) Visual Effect of Mountain Ridgeline

With continuous increases in heights for four different scenarios, three blocked sightlines only existed in S4 at the vantage point of Quarry Bay Park (Fig. 15). Besides, a further step was conducted based on the three blocked sightlines. A maximum area was designed to calculate the blocked sightline in red from the leftmost to the rightmost side with a much smaller interval of 0.01°, which means that the sightlines within this angle area should always be blocked. Following a number of new blocked sightlines, the summation block angle of all angles between adjacent sightlines within this block area was calculated. Finally, a block percentage was calculated for each sightline bundle (left is 1.36%, middle is 1.4%, and right is 1.58%). This result indicated that the visual effect on conservation of ridgelines was relatively small after the increasing PR/BH.

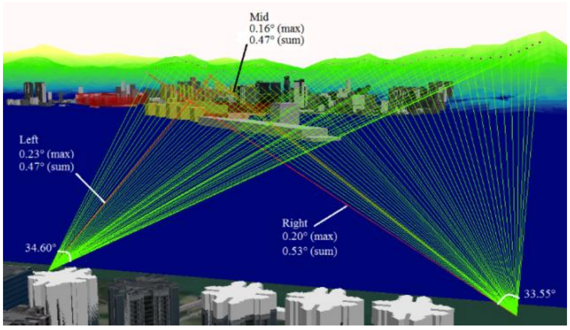

Figure 15: The situation of the Quarry Bay Park vantage point

3) Shadow and Solar Exposure

The average sunlight hours per day were calculated for the three study areas. The findings are presented in 3D environment within the chosen analysis regions in summer (Fig. 16). Specifically, ten classes of sunlight hours ranging from (0, 1] to (9, 10] are shown in different hues. These findings revealed that the differences between S2 versus S3, S2 versus S4 were not evident.

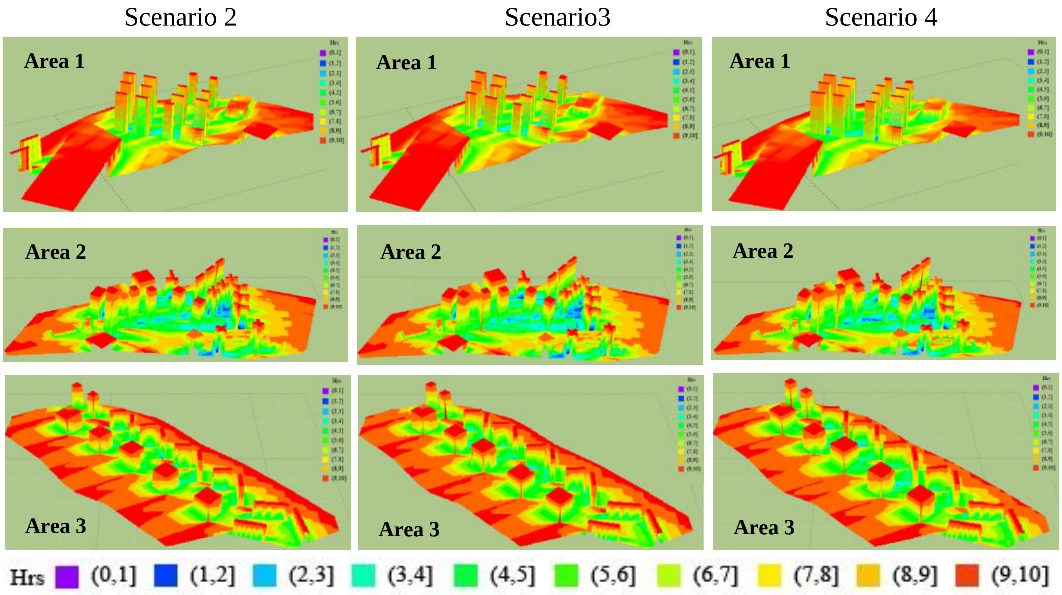

Figure 16: Results of average sunlight hour per day in summer

To further analyse the variation trend of sunlight hours for different scenarios, the differences in area range and related percentage between S2 versus S3 and S2 versus S4 were calculated and described in blue and red curves in Fig. 17, respectively. However, a consistent trend was observed. The two curves illustrate the difference in long sunlight categories; for example, (9, 10], (8, 9], and (7, 8] decreased because of the increased PR/BH. For short sunlight categories, such as (3, 4] and (2, 3], the difference increased accordingly. The fluctuations in the vibration rate were almost 0% for the shortest sunlight category. Moreover, the vibration rate of hours in middle categories such as (6, 7], (5, 6], and (4, 5] may not be fixed for different study areas because of the various distributions and directions of buildings. During this middle category, Sunlight hours increased in Areas 1 and 3, but decreased in Area 2, possibly because the spacing between the buildings in Area 2 was relatively larger than that in Areas 1 and 3. In general, all changes were insignificant, which demonstrated that the effect of increased PR/BH on shadow and solar exposure in summer was relatively small.

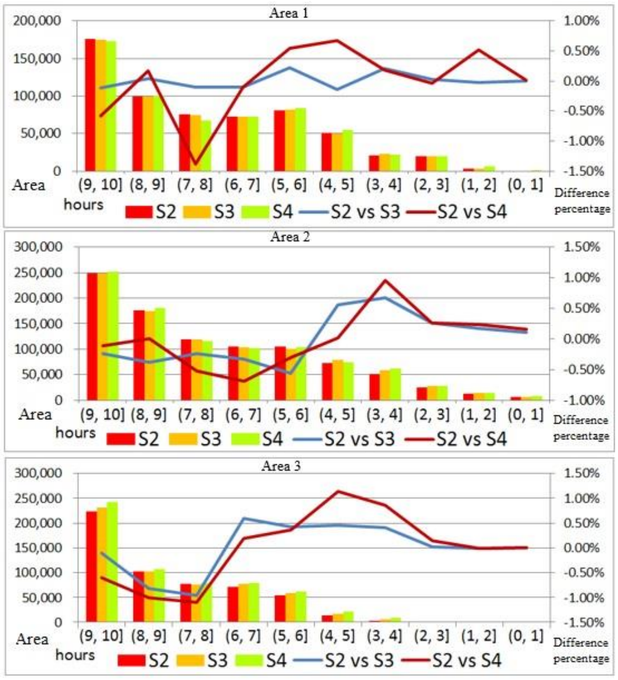

Figure 17: Sunlight hours and areas comparison in summer

4) Wind Ventilation and Air Temperature

To understand the extent of changes in different scenarios, various simulations were carried out in winter night as an example. The temperature range (−0.20 °C to 0.020 °C) presented in the legend in white is defined as an insignificant change. Air temperatures outside that range (below −0.20 °C in green or above 0.20 °C in red) were deemed significant changes. Fig. 18 shows an insignificant change in air temperature for most areas between S3 versus S2 and S4 versus S2. A small part of the red area is presented only for the upper left corner of Area 2, which indicated a slight change in air temperature between 0.2 °C and 0.3 °C in this area after increasing building height.

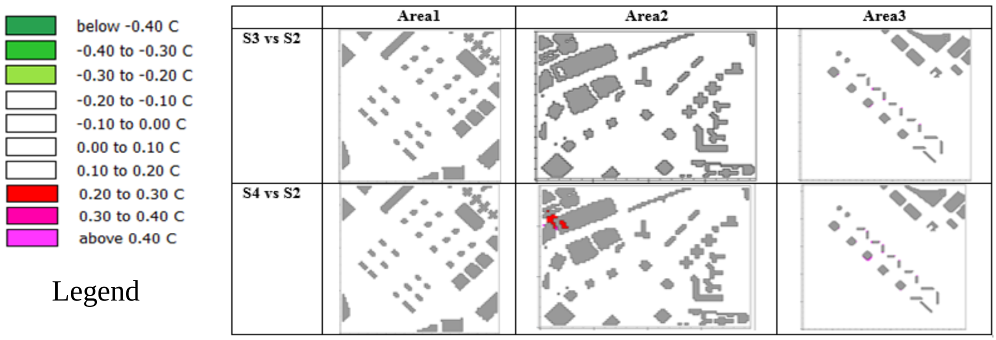

Figure 18: Air temperature comparison in different scenarios in winter night

Similar to air temperature, the difference in wind speed was also classified into different intervals. According to the subjective response to air motion (Bradshaw, 2006), the minimum wind speed that can be detected by human beings is 0.25 m/s, and the speed between 0.25 and 0.51 m/s that can be sensed by people is considered comfortable. Except for wind speed, wind direction in the study areas was also simulated and symbolized by the arrows, where a long arrow represents a fast wind speed.

As shown in Fig. 19, Areas 2 and 3 both showed some changes in wind speed. The extent of increase/decrease became more obvious in S4 versus S2 in the winter night. The decreased wind speed was due to the increase in building height, which blocked the wind. Meanwhile, increased wind speed was possibly due to the enlarged height difference between tall buildings and adjacent low buildings after the increase in PR/BH. According to wind direction, a southeast wind was defined for initialization during this simulation. The changes in wind direction depend on the site conditions, including position and layout of the buildings. As shown in Fig. 19, wind direction slightly shifted to allow wind to pass through the buildings. Finally, the findings indicated only small changes both in wind speed and wind direction for the three study areas, but more obvious changes were observed in Areas 2 and 3.

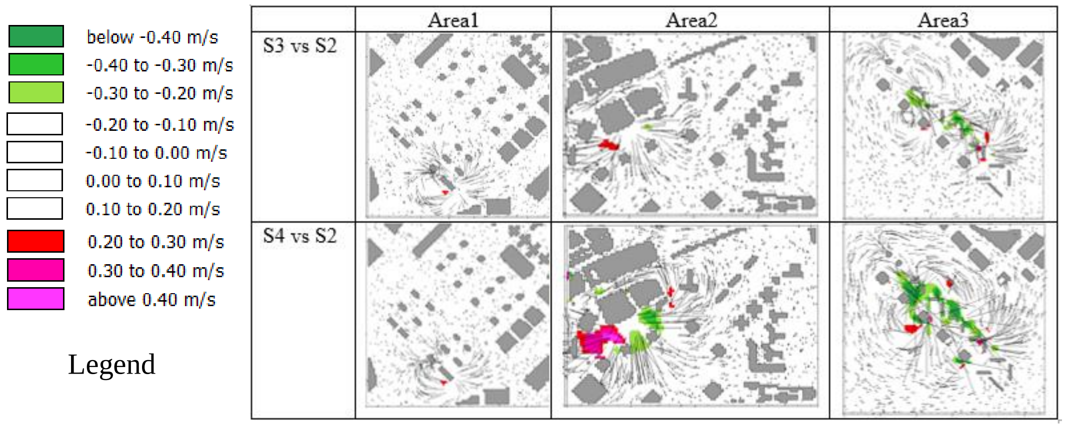

Figure 19: Wind speed comparison in different scenarios in winter night

5 Discussion

For wind speed analysis, more obvious changes were presented in our findings. Both increased and decreased wind speed appeared in Areas 2 and 3. The difference in wind speed was around 0.4 m/s, which was within the comfortable range sensed by humans (0.25–0.51 m/s), so the results were still identified as slight changes.

To prove the effects of minor relaxation of the maximum PR/BH restrictions of 21 target sites, 3D modelling and simulation technology were employed. However, only primary and simple 3D models were generated in this study. Therefore, more complicated and realistic 3D models should be produced and designed in terms of different building structures, materials, suitable layout and directions, and podium and car park employment for further studies. Besides, the simulation of thermal properties of buildings, types of gas sources, and energy source in water bodies was limited, which resulted in a less accurate simulation compared with the real case. Furthermore, more ideas about the formation of numerical model and microclimate can also be investigated in the future.

6 Conclusions

3D modelling and spatial analysis technology were introduced in this study to conduct simulations based on 3D models, which could aid in people's understanding and provide more vivid visualizations than 2D GIS. The effects of increasing PR/BH toward urban skyline, visual effect of mountain ridgeline, shadow and solar exposure, air temperature, and wind ventilation for the three target study areas in four scenarios were successfully observed. Based on the findings of various spatial analyses, minor relaxation of the maximum PR/BH led to the following conclusions.

(1) Urban skylines were drawn to check the city profiles of the three study areas in four scenarios. The effect of increasing PR/BH on urban skylines was not significant, which was reasonable and acceptable.
(2) Sightlines were generated by connecting the selected vantage points and sampling points on the mountain to check the visual effect of mountain ridgeline. With continuous increasing height for the four scenarios, the blocked sightlines only existed in S4 at the Quarry Bay Park. Three bundles of sightlines were blocked. Based on the figures, a very slight visual effect was noted on the conservation of ridgelines.
(3) During shadow and solar exposure analysis, the conditions in summer were considered for the whole study areas. The average sunlight hours per day, sunlight area size, and corresponding percentages for different categories of sunlight hours were calculated and presented by figures. The findings showed that the changes were insignificant, which indicated that the effect of shadow and solar exposure to the surrounding environment in summer was relatively small when we increased PR/BH.
(4) For air temperature, only a slight change appeared in Area 2 in summer night. The changes were between 0.2 °C and 0.3 °C.
(5) For wind ventilation, more obvious changes were shown in wind speed and direction for Areas 2 and 3. However, the magnitude of change in wind speed was only that sensed by humans and deemed as a comfortable change. Therefore, only slight changes were observed when increasing PR/BH for the study areas.
(6) The findings of 3D spatial analyses revealed that S4 was the recommended reasonable scale for relaxation of the maximum PR/BH restriction for the 21target sites in the KTDA.

The use of 3D modelling and spatial analysis technology provides people with a more holistic view and allows them to make more effective and informed decisions. The method proposed in this paper can also be applied in urban renewal studies or new development areas in other densely populated cities similar to HK.

Introduction of sustainable low-cost housing. Experiences from a demonstration project viewed from an innovation diffusion perspective

Bengt Hjort, Pontus Petersson, Teferi Sendabo, Kaleb Ström and Kristian Widén

Halmstad University, Sweden
Email: bengt.hjort@hh.se

Abstract

The purpose of the study is to describe and analyse, from an innovation diffusion perspective, factors important when using demonstration projects as a tool for introduction of sustainable low cost housing. The study is focused on Ethiopia, a country with big challenges as regards population increase, lack of resources, deforestation, land erosion and a general need for better and sustainable housing, especially in rural areas. The study is furthermore focused on the adobe technology as a more sustainable alternative to the traditional building technology which is very timber consuming. Many attempts have been made to introduce this technology with the use of demonstration buildings. A great part of these attempts have failed, some have been successful. In order to study and discuss important factors in connection with the use of demonstration buildings, a project executed some years ago in southern Ethiopia has been analysed. The study is based on findings collected during and after the erection of these buildings mainly through practical tests, interviews and observations. From a technical point of view this demonstration project was successful. It was possible to develop an appropriate production technology and the result was buildings with a good standard and good function. Experiences up to now indicate a good durability. From an innovation diffusion perspective however the demonstration buildings have not fulfilled their purpose. The impact in the region seems to be very small. The conclusion in the paper is that the reasons behind this failure mainly are: (1) Lack of clear and visible relative advantage in comparison to the traditional building technology. The supply of construction timber in the area in question is still good. (2) Lack of a champion advocating the technology by using the demonstration buildings and thereby giving the message to the society that the technology is valuable and trustworthy. (3) Lack of continuity in the demonstration efforts, as a result of the lack of a champion.

Keywords: innovation diffusion, adobe, demonstration project, sustainability, low-cost

1. Introduction

Ethiopia is currently ranked as number 174 of 187 countries in the world by the Human Development Report (2015). The ranking is based on a Human Development Index which is a composite index measuring among other things the standard of living. The low ranking indicates difficult living conditions for the vast majority of the inhabitants of Ethiopia. This is caused by current serious problems such as a very large population with a high population growth rate putting a high pressure on already inadequate resources causing e.g. high rate of deforestation, (Barton and Dlouhá, 2014).The deforestation in its turn causes other problems and difficulties, e.g. land erosion and lack of suitable timber for construction, (Barton and Dlouhá, 2014).

In 2011 the Ethiopian Government issued the document "*Ethiopia's Climate-Resilient - Green Economy. Green economy strategy*" (2011). In this publication it is stated that Ethiopia aims to achieve middle-income status by 2025. The aim is to develop a climate-resilient green economy by avoiding sharp increases in greenhouse gases (GHG emissions) and unsustainable use of natural resources.

A vast majority of the Ethiopians, about 80%, are living in rural areas. This means that a majority of the Ethiopians have rather bad housing conditions. A study by Kumie and Berhane (2002) indicated poor living conditions for many persons living in rural areas, with overcrowded houses with poor sanitation conditions. The authors stress that this fact predisposes to adverse health conditions and that appropriate interventions are needed.

As regards the Ethiopians living in urban areas the average situation seems to be better with a much bigger variation in living standard from case to case; (Abelti et al, 2001) and (Bihon, 2007). Anyhow, the need of improvement is great also for urban areas.

From what is written above it is obvious that there is a great need to improve the housing conditions for many Ethiopians. New methods for erecting dwelling houses must be introduced. These methods must be sustainable and take into account the present situation in the country and the Ethiopian Governments aims regarding GHG emissions and the sustainable use of natural resources. In addition to this, the methods must result in durable and safe dwelling houses that have a healthy indoor climate. A technology that is interesting in this context for erection of walls is the adobe-technology.

During the years several attempts have been made to introduce this technology in Ethiopia. Many times demonstration buildings have been erected in connection with the introduction. Some of the attempts have been and are successful, many have been failures.

The aim of this paper is to present and discuss from the innovation diffusion perspective factors of importance for the introduction of adobe-technology technology in Ethiopia. The discussion is based on findings and experiences from a demonstration project executed during the years 2009 – 2012. The aim of the demonstration project was to introduce this technology in a region in southern Ethiopia. The data from this demonstration project presented in this paper was collected mainly thorough practical tests, interviews and observations.

2. Innovation diffusion

Innovation has been defined in many ways, in different contexts, but all are more or less pointing in the same direction, with slight differences. One definition that has gained a wide acceptance is “the implementation/adoption of new or significantly improved production or delivery methods” (OECD, 1997). It is useful as it links innovation to value creation and recognize this in a broader sense than short-term economic perspectives, as well as move away from the linear process best measured by R&D spending (Loosemore, 2014). That makes it also useful in this context. Innovations evolve in an economic, social, cultural and political context and are highly influenced by this (Weisenfeld, 2003). This explains why innovation vary between different contexts such as industry, political, national etc. This suggests that different national contexts when transferring an approach or technology between contexts, for example when transferring between countries, need to be addressed (Abdul-Azis, 2002). Developed and developing countries have to address different problems in relation to innovation (Bröchner, 2011). Differences in education, communication, business maturity etc all affect innovation. As learning is a central to innovation, and it is a social activity, which involves interaction between people (Lundvall, 1992) it is important to have a supporting framework around the innovation project or innovation diffusion project suited to the context enabling people to learn about the innovation.

Undertaking construction innovation outside of projects appears to be a very unusual process (Tatum, 1987). This result in that innovation in construction, from a process perspective, is complex and involves different stakeholders and components (Manseau, 2005). From a technical perspective the innovation in the current context is not as complex as in most western countries, but the process may be as complex, but in other ways. The development of a collective understanding of the innovation and building trust at the operational level where individuals are more likely to encounter it is important. A critical success factor is involvement, from the early stages of development, of those who will be responsible for implementation, possibly requiring mediation between new development and existing routines and duties within the organizations affected (Barlow et al., 2006).

In an earlier study where common areas of importance for the diffusion process, compare with Stoneman (2001), have been applied on non-commercial innovation diffusion in developing countries, it was found that the factors, apart for commercial factors, are applicable (Hjort and Widén, 2015). Those cases where there was a champion, where there was a “market”, a need, where the cultural context allowed for the innovation, the diffusion succeeded. In the cases where a majority of the factors were missing the diffusion failed. Other factors that may be of importance for diffusion, not specifically studied in the earlier work, are relative advantage, compatibility, complexity, trialability and observability (Rogers, 2003). Relative advantage is how much better the innovation is perceived to be than the technology it is supposed to replace. Compatibility is the extent an innovation fit within the existing values, past experience and needs of the adopters. Complexity addresses how difficult the adopter finds the technology to use. Trialability deals with the adopters’ potential to experiment with the technology. Observability is about how the results are visible to others. Some of these factors are to some extent overlapping the factors tried earlier, for example relative advantage share much with if there is a market. The market will be there if there is a relative advantage of the innovation. Compatibility has some parts in common with the cultural dimension. Does the innovation fit into the contextual setting where it is to be diffused? Whereas complexity, trialability and observability are not dealt with to the same extent explicitly in the earlier study, compare with Hjort and Widén (2015).

3. Alternative building technologies

The traditional way of erecting a dwelling-house in Ethiopia is to use a framework of timber in the walls. Timber-poles with an appropriate length are put into the soil. The timber-specie mainly used varies from region to region according to availability. In the highlands the timber-specie mainly used, has been and still is fast growing Eucalyptus. However, in order to enhance the durability of the walls, some poles of more durable timber species, have been used in the walls with a spacing of approximately 1000 mm. The framework is provided with a roof structure which is covered with grass or corrugated iron sheets. This framework is later on covered with mud mixed with straw. Sometimes one of the last steps in the process is to provide the walls with a "foundation". This is done by arranging a stone masonry around the outer walls. It is clear that this masonry actually is not a real foundation but protection of the lowest part of the walls. The timber core of the walls are in contact with the soil and can thereby be exposed to termite attack and decay caused by high moisture content. With regard to this the use of more durable timber in the walls is crucial.

Dwelling houses that give a good indoor climate and that are reasonably durable can be erected if these houses are provided with a proper foundation and sufficiently long roof overhangs. Despite this it is very doubtful if this technology can be used on a broader scale in the future. There are important reasons for this standpoint. Firstly, the traditional technology is very "timber-consuming". With regard to the current de-forestation in Ethiopia and resulting timber-shortage, it seems clear that an alternative technology must be used. Secondly, the possibility to obtain durable timber species, traditionally used in connection with construction of walls, e.g. Thid (*Juniperus Procera Hochst*) and Kosso (*Hagenia Abyssinica*), will be very limited in the future, (Bekele et al, 1997). Because of the ongoing deforestation such species are very difficult to obtain, at least to a reasonable price. This has had, and will have, a serious impact on the possibility for ordinary people to erect dwelling houses with framework that could resist termite-attack and decay.

The termite problem, which is underlined in Berhane (1984), seems to have be a growing problem in Ethiopia a rather long time. A rather recent study on termite damage on rural housing in the Central Rift Valley in Ethiopia, (Debelo and Degaga, 2014), confirms this. According to this source the wood/straw thatch buildings characteristics of farming communities in Ethiopia, are susceptible to termite damage, particularly in the tropical savanna areas. They forward a source, (Abduraman ,1990) which reports that in western Ethiopia, where the termite problem is accentuated, thatched roof huts are destroyed in less than five years and corrugated iron roof houses in less than eight years.

A realistic alternative to this traditional building technology is to use adobe blocks for the walls, i.e. to build walls in dwelling houses with sun-dried blocks made of mud; with or without straw included.

The technology is not a traditional technology in Ethiopia as a whole, although there are some areas where the technology has been in use for a rather long time, e.g. in the eastern Ethiopia.

In a recent study, (Petersson and Ström, 2015) the spread and diffusion of this technology in some locations in the eastern, the central, south-central and western parts of Ethiopia has been analyzed. As regards the diffusion, adoption and spread of the adobe technology the main of the study result can be presented as follows:

- In some parts of the country, mainly rural, there is a development which can be described as a spontaneous spread of the technology. The technology is commonly adopted and the driving force behind this development is clearly the present effect of deforestation – lack of construction timber at reasonable prices. This is the case in some parts in Eastern Ethiopia and in the Central Rift Valley.

- During the years a number of initiatives have been taken in order to introduce the adobe technology in Ethiopia, both in rural areas and in urban centers. The erection of demonstration buildings has been an important part of these initiatives. Most of these initiatives seem however to have failed, as they have not resulted in a sustainable diffusion of the technology. The reasons behind this are many and interdependent. Petersson and Ström (2015) mention, among other things the following: lack of continuous efforts, neglecting of training and education, market forces, negative attitudes from authorities and absence of advantages that are easily and clearly identified.

- In some cases the adobe technology has been used in a way that is not recommendable from a technical point of view. The reason behind this seems to be a lack of understanding of the limitations of adobe and a lack of experience. It can be anticipated that cases like these creates negative demonstration that limits further diffusion of the technology instead of promoting it. These observations underline the importance of proper demonstration and education.

Several cases in Ethiopia, see e.g. Hjort and Sendabo (2007), show that durable houses with a good indoor climate can be built by a proper use of adobe technology. The technology has many advantages: it is real low-cost, local material can be used to a very great extent and the “timber content“ is very low. In addition to this it is rather simple with no need of special equipment with the exception of some simple forms for block-making. The technology has really the potential to become “the property of everybody”.

As regards durability however a special concern must be given in some regions to termite-attack also for adobe-houses. This is clearly demonstrated by Debelo and Degaga (2014). In connection with site-visits in Central Rift Valley in Ethiopia they have noted that more than 85 % of 35 houses built by mud blocks where prone to termite infestation. The corresponding figures for 23 houses built according to the traditional technology was 100%. It can be noted that the great majority of the houses, both adobe and traditional, were rather young, i.e. less than six years old.

Debelo and Degaga (2014) argue that it is more likely that infested wooden wall houses have a shorter life then adobe houses as they attack the load bearing structure, the wooden wall. However, also in adobe houses, the termite can cause serious problems. In adobe walls they can simply move through the walls without affecting these and the roof structure and cause heavy damages.

4. The demonstration project

At Halmstad University studies concerning low-cost housing with a special focus on the Kambaata Region in South Central Ethiopia have been conducted for several years; (Hjort and Sendabo, 2004). The overall aim has been to introduce low cost housing technologies and at the same time study and analyse the attitudes of ordinary people towards these technologies. From the beginning the importance and necessity of erecting demonstration buildings have been underlined.

In accordance with this a project aiming at erection of four demonstration buildings in the town of Durame in the Kambata Region was initiated. The aim was to study and demonstrate two low-cost housing technologies; adobe technology and a technology based on cement stabilised soil blocks. The purpose was to get a basis for technical studies as well as studies concerning attitudes. The technology based on cement stabilised soil blocks will not be commented further in this paper.

When the project started the adobe technology was by and large unknown in the Kambaata Region. Although this region was and still is densely populated, the access to timber for construction purpose was and still is rather good, at least as concerns eucalyptus. This means that an important driving force for a spontaneous development of the adobe technology was and still is lacking.

The project was planned and conducted in cooperation with a local development organisation. The plan was that this organisation should own and use the erected demonstration buildings in the future. The work at the site started in the beginning of 2009. Due to different difficulties the project was delayed and the demonstration buildings were not finalized until the beginning of 2012.

The studies related to these demonstration buildings can be divided into two groups: studies which focuses on technical issues and studies related to attitudes towards the new technologies. They have been executed before, during and after the erection of the demonstration buildings, see Table 1.

Table 1. Studies within the project – overview.

Type of study	*Before erection*	*During erection*	*After completion*
Technical studies	*Trial tests of soil reported in Andersson and Berglund (2002)* *Laboratory and field tests regarding adobe blocks; reported in Hjort (2009).*	*General observations with focus on methods for weather protection during manufacturing of blocks and masonry work of walls.*	*Follow-up studies that will focus on durability and function.*
Studies regarding attitudes		*Observations* *Inquiry form*	*Observations* *Interviews.*

The detailed design of the demonstration buildings was executed by two BS.C students. It is described in Johansson and Wartainen (2008). These two students based their design from findings obtained during a field study in Ethiopia. An essential part of their field study was a visit to Challia in Western Ethiopia, where they studied a successful low cost housing project. Interviews with people living in houses erected by adobe technology were an essential part of their study.

Three buildings were designed according to the following:

- Buildings: Dwelling House, Kitchen and Toilet:
- Sizes: Dwelling House : 5,5 x 5,8 m^2, Kitchen: 3,4 x 3,4 m^2, Toilet: 2,5 x 2,5 m^2
- Foundation: Stone masonry for all buildings
- Walls: Adobe;
- Roofing: Trusses of eucalyptus. Corrugated iron sheets for all buildings
- Flooring: Concrete slab on natural stone for all buildings
- Ceiling: Dwelling House Of cloth
- Doors and Windows: Wooden. Locally fabricated for all buildings

This is a description of the main features of the design. However, many important details are discussed and appropriate solutions are proposed by Johansson and Wartainen (2008). The following can be mentioned: foundation details, roof overhang, securing of roofing against wind-forces, fastening of door and windows.

The soil available at the spot was used for the production at the site of adobe blocks with the size 150 mm x 200 mm x 400 mm. The soil, taken at a depth of about 500 mm after the topsoil had been removed was mixed with water and straw. The straw, consisting of" teff-straw" was purchased locally. Simple forms made of ply-wood were used. These forms were open in the bottom and in the top. The manufactured blocks were stored and cured, at a first stage inside a store and at a second stage under a weather protection roof, see below. The expected and intended curing time was 28 days. However, for some of the manufactured blocks this time was prolonged considerably due to rainy and thereby humid air conditions. As mortar in the adobe walls soil mixed with water and straw was used.

The weather in Durame and its surroundings seems to have become unpredictable. Because of this the erection of a temporary roof structure was necessary as adobe blocks are very sensitive against water and wetting up. Because of this, and because of difficulties in planning the project work in relation to rainy periods, a temporary roof structure acting as weather protection was erected for the Dwelling House. This temporary roof structure consisted of the final roof structure (eucalyptus trusses, eucalyptus purlins and corrugated iron-sheets) for the building in question resting on temporary eucalyptus poles. The manufactured blocks were in a first stage stored below this temporary structure. In a second stage the walls were erected below it. At a final stage the roof structure was made to rest upon the walls and the eucalyptus poles were removed.

The general impression and experience from the use of this technology in Durame is that it is very suitable for the region and that it is easily understood and easily adopted by workers involved. The manufacture of adobe blocks and the erection of the buildings arouse a great interest among the inhabitants of Durame and most people expressed a positive attitude towards the technology.

In Table 2 the result from a questionnaire regarding the attitude towards the adobe technology is presented. The questionnaire was written in the official national language amharinja and in the local language kambatinja. It was made with the erection of the demonstration buildings as a reference. The questionnaire was distributed to 40 persons whose answers were analysed.

Table 2. Studies of attitudes towards adobe technology

Part	***Statement***	***(%) responding positively***
Regarding the acceptance of adobe technology	*I don´t support the idea*	*5*
	I support the idea	*93*
	I support the idea but I don´t think it will be accepted	*2*
Regarding training in adobe technology	*I am willing to participate*	*90*
	I am not willing to participate	*5*
	Before I answer – let me see the training	*2*
	No answer	*2*

5. Follow-up studies

During a visit in the beginning of 2015 to Durame observations and semi-structured interviews in the region were made. The observations showed that from a technical point of view the demonstration buildings were in good condition. Some defects were however noted, e.g. has the cement-lime plaster on the walls, which is intended to protect the walls from rain, come loose. It was also noted that the demonstration buildings were not used; neither by the local development organisation in its daily business, nor as demonstration objects related to ongoing education regarding adobe technology.

At an interview with a person representing the local development organisation it was mentioned that this organisation, due to lack of resources, had not been able to utilise the demonstration buildings as intended from the beginning. One of the intentions had been to continue with educational activities within adobe technology with the use of the demonstration buildings as reference objects.

The observations indicated further that the impact of the project and the demonstration buildings with regard to introducing the adobe technology in Durame and its surroundings was very small, if any. This impression was confirmed by interviews. At the interview with the person representing the local development organisation it was stressed that the adobe technology would have big advantages as a building material in the Durame region but that it has not been adopted by the local population mainly due to lack of knowledge.

6. Concluding discussion

The project showed that it is possible to erect durable and functional adobe buildings in the Durame area. Appropriate material is available and the technology can easily be understood and adopted by local workers. Furthermore, it showed that it is possible to handle the somewhat unpredictable weather conditions in the area by erection of a temporary roof structure that later on can be transferred into the permanent one.

The outcome of the project with regard to introducing a new technology can be discussed and analysed from an innovation diffusion perspective based on the attributes defined by (Rogers, 2003):

"***Relative advantage".*** The relative advantage of the adobe technology, in relation to the traditional technology, might be underestimated or even denied by ordinary people in Durame. In this region there is no shortage of timber for construction; one of the main driving forces behind the spontaneous spread of the technology in other regions in Ethiopia. Other advantages, such as a better indoor climate and a better resistance against termite attack can only be perceived by the use of the building and after a longer period respectively.

*"**Compatibility" .***The adobe technology can be regarded as a compatible technology as mud mixed with straw is a very important part of the traditional building technology. In accordance with this working with mud has a long tradition in Ethiopia. However, working with clay has low status in Ethiopia; (Hjort and Sendabo, 2005). This might deter potential users from building their dwelling house almost entirely of mud.

*"**Complexity".*** Adobe is a simple technology; it is easy to understand and it is easy to adopt as clearly demonstrated during the erection of the buildings. However, the use of a temporary roof structure as a shelter and as a storage area and later on using this as permanent roof structure might have been regarded as complicated and difficult. It is possible that this part of the process has deterred potential users from adopting the technology.

"***Trialability".*** The adobe technology offers a good trialability as such. It is thus possible for a potential adopter to try the technology in small scale, for instance by using it for a minor building, e.g. for a store or similar. In this case this has only been done when executing the demonstration project. The reason for that is that the organisation championing the diffusion had to withdraw earlier than planned.

*"**Observability"*** The adobe technology offers a good observability of its buildability which was used in connection with the demonstration buildings erected in Durame. But, the observability of the finished product, its durability, indoor climate etc has to be observed for some time, years. As the building has not been used and the organisation championing the diffusion withdrew this has not been done in this case.

From a comparison between this study and the study presented in Hjort and Widén (2015) it is clear that the role of a champion is very important as is the perceived relative advantage and the cultural context. In this case several of the factors pointed out by Rogers (2003) was not fulfilled, but could, or would, have been if a champion had been present over time, also after the demonstration project finished.

This study, together with the earlier study, forms an interesting base for future studies of non-commercial innovation diffusion in developing countries. In future studies the focus will be on the role of the champion of the innovation over time, the role of relative advantage and the cultural context and how these influence the success of diffusion, as well as how these influence the other factors said to be important for innovation diffusion.

Advanced Intelligent Agents for Optimised Dynamic Process Monitoring and Defect Inspection in Construction Projects

Farzad Pour Rahimian, Jack S Goulding, Gary D Holt and Bogdan Matuszewski

School of Engineering, University of Central Lancashire, Preston, UK.
Email: fpour-rahimian@uclan.ac.uk

Abstract

Defects and errors in new or recently completed work continually pervade the Architecture, Engineering and Construction (AEC) sector. Whilst inspection and monitoring processes are established vehicles for 'control', the procedures involved are often process-driven, time consuming, and resource intensive. Paradoxically therefore, they can negatively impinge upon the broader aspects of project time, cost, and quality outcomes (the three central tenets). Acknowledging this means appreciating concatenation effects such as the potential for litigation, impact on other processes and influence on stakeholders' perceptions – which in turn, can impede progress and stifle opportunities for process optimisation and innovation. This also deleteriously affects opportunities for improving: logistics, carbon reduction, health and safety, asset underutilisation, and labour distribution. This study evaluates these challenges from a time, cost, and quality perspective, focusing on identifying opportunities for process innovation and optimisation. It reviews the state of the art technologies that support optimal use of artificial intelligence, cybernetics, and complex adaptive systems within the AEC sector. From this, a conceptual framework for the development of a real-time intelligent observational platform supported by advanced intelligent agents (RtIOP), is presented as a solution to these challenges. RtIOP actively, autonomously, and seamlessly manages intelligent agents (e.g. cameras, RFID scanners, remote sensors, etc.) in order to identify, report, and document 'high risk' defects. Findings underpin a new ontological model that supports ongoing development of a dynamic, self-organised sensor (agent) network, for capturing and reporting real-time construction site data. The RtIOP model is a 'stepping stone' towards the advancement of independent intelligent agents, embracing sensory and computational support, which are able to perform complicated (previously manual) tasks to optimise dynamic processes seamlessly and autonomously.

Keywords: Intelligent agent, process, innovation, ICT, sensors, optimisation

1. Introduction

Defects and errors within the AEC sector still continually pervade the industry. Whilst detailed inspection and monitoring processes are established vehicles for their 'control', the procedures involved are often process-driven, time consuming, and resource intensive. These checking and monitoring processes can negatively impinge upon the broader ambitions of project time, cost, and quality outcomes as they are very resource-intensive. In recent years, the trade-off between an increasing need for non-stop inspections during construction work and their negative ramifications have focussed on the ‘value’ of systematic, innovative monitoring of construction operations (vis-à-vis conventional ‘inspector-based’ methods). Research in this area has attempted to address this through various proffered systems, typically embracing the ability to automate, capture, process and share project data among relevant stakeholders.

These systems have provided additional project benefits, for example improved: logistics, carbon reduction, health and safety performance, project efficiency savings, increased asset utilisation, and smoother labour distribution. However, unlike other industries, the AEC sector has not been quite as successful in adopting such automated monitoring systems; especially, for small and medium scale projects (Navon and Sacks, 2007). This is mainly due to the: nature of construction products (Howell, 1999); unsuitable nature of construction sites for high-tech monitoring solutions (Cheng and Chen, 2002); disaggregated nature of construction project teams (Davidson and Skibniewski, 1995); and slow, error prone existing project data collection systems (Saidi *et al.*, 2003).

Given these challenges and associated conditions, the majority of construction projects retain their protracted and inaccurate traditional (inspector reliant) control mechanisms. Among other things, this leads to a lack of ‘as-built’ construction project information (Saidi *et al.*, 2003) – which results in a general disorganisation of projects in relation to schedule, cost, and workforce control (Howell and Koskela, 2000). Acknowledging these issues, this study evaluates these challenges associated with current technologies from a time, cost, and quality perspective. The overall focus is to identify opportunities for the introduction of hybrid low cost systems which are specifically able to optimise the monitoring and control process; thereby allowing significant innovation opportunities to occur.

2. Related Works

This section overviews the state of the art technologies for facilitating systematic onsite monitoring of construction projects. In pursuance of this, it should be noted that regardless of the core functions and associated technologies, the majority of thinking on monitoring and control systems can be categorised into two groups: 1) Tracking or Scanning Equipment based technologies; and 2) Still Image based technologies. The challenges and opportunities of these two categories are presented as a prelude to making recommendations for the development of a hybrid, intelligent monitoring system (RtIOP).

2.1 Tracking or Scanning Equipment Based Technologies

There are a myriad tracking or scanning technologies available to facilitate systematic and automated construction project monitoring. One popular example is the Global Positioning System (GPS) which can be widely used to determine the geometric properties of a constructional element e.g. equipment within a construction site. Others include for instance, augmented reality (AR) (Chi *et al.*, 2013). These systems are now being used for tracking and managing the workforce (Hammad *et al.*, 2009), as well as monitoring and helping control the implementation of constructional elements (Behzadan *et al.*, 2008). Additional similar functions are supported by technologies such as Radio Frequency Identification (RFID) (Kelm *et al.*, 2013), Ultra-Wide Band (Zhang and Hammad, 2012), and Barcoding (Chen *et al.*, 2002). Hybrid systems use a combination of these options; such as when GPS is merged to work alongside RFIDs (Kelm *et al.*, 2013). Despite their merits, the reliability of such systems has always been something of a challenge, since they can be affected by unexpected interfering fields (Chi *et al.*, 2013). Another downside is the comparatively high capital investment needed for such equipment, which in many cases ultimately becomes 'buried' in the completed construction facility – which can add significantly to the overall project cost.

An alternative system relies on laser-scanned point clouds. Laser scanning is not a new technology, but due to the increasing take up of Building Information Modelling (BIM), as-built BIMs scanned by these tools are gaining popularity, with increased use being acknowledged within the AEC sector. This is mainly because they are capable of measuring geometric characteristics of environments, with high accuracy and within short timescales (Tang *et al.*, 2010). The as-built BIM generation – which is also known as 'scan to BIM' – is described by Tang *et al.* (2010) as a process comprising the following: 1) data collection through dense measurement of points about the building using laser scanners; 2) data pre-processing, which includes filtration of point clouds and the integration of coordination systems; and 3) modelling the BIM, which is a process of transforming the point clouds to semantically rich BIM objects. The downside of as-built BIM technology is that whilst data pre-processing is a fairly straightforward process, the data collection and modelling tasks are often very costly, time consuming and error prone (Bosché *et al.*, 2015; Brilakis *et al.*, 2010). These challenges have made many scholars to suggest Still Image based technologies as a viable alternative.

2.2 Still Image Based Technologies

Advancements in technology and the declining prices of mobile and fixed cameras have encouraged the increased use and uptake of photography to record daily activities and progress of construction projects. This also includes monitoring, logistics, documentation, and control purposes (e.g. resource management, Health and Safety etc.). This has also underpinned the emergence of new photographic documentation and distribution services, to provide 'visual' progress records for efficient distribution among stakeholders (Han and Golparvar-Fard, 2014). With the aid of multi-view geometry methods, image processing, and computer graphics, these 'as-is' images can either be compared with one another throughout the construction process or against an ideal 'to be' 4D BIM, which represents the assumed flow of processes. These options help flag up possible deviations (e.g. errors) in construction works (Yang *et al.*, 2015).

Due to their distinctive benefits, for example cost efficiency, accuracy, and reliability – such systems are increasingly popular. This popularity includes: detection and recognition of building elements (Chi and Caldas, 2011; Gong and Caldas, 2011); tracking 2D and 3D positions of objects (Hu *et al.*, 2004); controlling and monitoring site activities (Rezazadeh Azar *et al.*, 2012); and managing productivity (Gong and Caldas, 2009). Their downside is however, that they are fully dependant on the quality and supply of the images – which can yield challenges due to volume regarding the need to continuously capture photographs with site data. These solutions can also be highly labour-dependent for systematic image capture when 'high-tech' equipment is not available. Another challenge can be access, especially to all parts of construction site; as in some cases this is not practically feasible.

3. Research Methodology

The research methodological approach adopted in the research includes a reflection on extant literature within the field of reference to evaluate the state of the art technologies employed within the AEC sector in order to capture the salient challenges facing researchers examining automated project appraisal. This process involved the selection of cognate discipline fields (see keywords) and text from seminal journals and core reports to not only identifying the challenges associated with each technology, but also the current thinking and future trajectories proffered. From these results, a theoretical propositions is presented for discussion. This was based on the scientific foundations required to support such systems, including the optimal use of artificial intelligence, cybernetics, and complex adaptive systems. The resulting conceptual framework (RtIOP) presents a typology, which includes software agents to access and address multiple data analysis tasks, including vision-based object recognition and tracking for construction monitoring.

4. Future Perspectives

Extant literature confirms significant achievements and emerging advancements, especially in computer graphics, 4D modelling, BIM, AR, big data processing, aerial robotics, cybernetics, and smart agents. These are now starting to pervade the market, and are starting to revolutionise construction project monitoring. However, whilst it could be argued that collaborative multi-agent systems for real-time monitoring and planning on construction sites is not particularly new (Zhang et al, 2009); there are still many challenges associated with seamless integration. In terms of computer graphics, Karsch *et al.* (2014) developed an interface based on the Structure-from-Motion (SfM) technique to automatically compute alignment of photos taken from a selected model. This engages automatic reasoning on both real-world construction data and established multi-view datasets.

Modern photogrammetry and remote sensing have a strong heritage (Thompson, 1977; Richards, 2013). However, new technological advancements and the declining costs of equipment - especially computer processing and visualisation, robotics and geomatics engineering has resulted in a an increase in the use of low cost accurate aerial systems for collecting and analysing geometric and geographic data (Colomina and Molina, 2014). Similarly, Siebert and Teizer (2014) developed an innovative programme for photogrammetric flight planning and control to generate 3D point clouds from digital mobile images. They evaluated the performance of a purposively developed Unmanned Aerial Vehicle (UAV) system, which was able to rapidly and autonomously collect 3D data.

With the aim of capturing large amounts of data with minimum manual input Zollmann *et al.* (2014) used a UAV system controlled by an automatic flight path planning programme. Larger UAVs were able to capture the whole geometry quickly; while smaller, less expensive vehicles were employed to capture more detailed, localised data from parts of the target boundary. Due to limitations in battery life for such vehicles, an optimisation algorithm for programming flight paths and task objectives was also designed (*ibid*.). Despite these kinds of valuable advancements for systematic use of UAVs on projects, issues of capital cost and the requirement for in-house expertise, puts their use beyond the capabilities of many construction projects.

Given these issues, it is postulated that these kinds of challenges can be overcome by employing a mix of artificial intelligence, cybernetics, and complex adaptive systems. Intelligently combined, these could support novel arrangements of independent equipment solutions (as smart agents), with sensory and computational resources to perform complicated tasks of dynamic data collection and analysis of construction projects. Within such a network, agents could take the form of any device capable of collating and communicating site data, such as still time-lapse or video cameras, RFID tags, GPS receivers, range sensors, and other type of sensors capable of localised sensing.

A set of optimisation agents for managing project resources would need to complement project targets, including delivery of just-in-time logistics; distribution and management of materials; and labour optimisation, across the entire works. The system would actively embrace the model of the ‘invisible hand theory’ (Minowitz, 2004), whilst also taking account of concomitant human factors typically engaged in site-related activities. A conceptual model of this RtIOP architecture is shown in Figure 1.

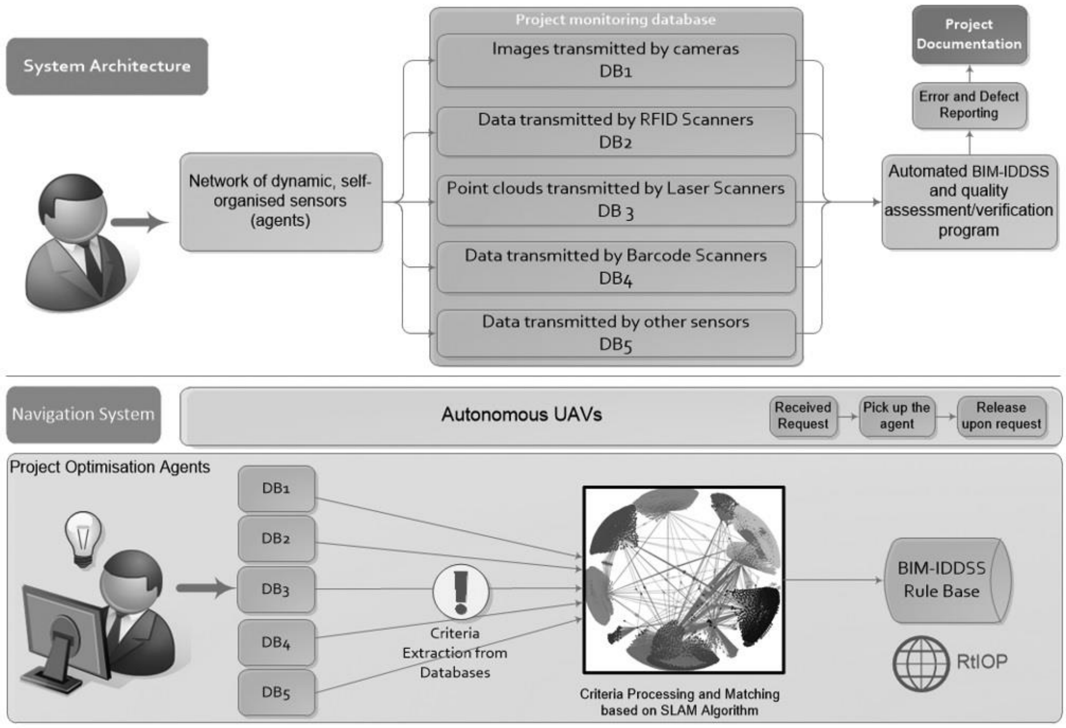

Figure 1. Conceptual model: architecture of the proposed intelligent project monitoring system

5. Discussion

In developing the conceptual model, specific consideration should be given to the optimisation of inter-agent communication and collaboration schemas, possibly in the form of a dynamic autonomous management tool. The system could have wide scope of application including identification, reporting, and documentation of defects and errors within a construction environment; monitoring of the construction progress; creation, maintenance and updating of the construction site materials repository; and optimisation and monitoring of workforce deployment.

The architecture of this system is envisaged to rely on a network of dynamic, self-organised sensors (agents) for capturing and reporting construction site data in semi or real-time. The network could consist of a set of multiple, autonomous ‘clip on’ sensing agents (including intelligent cameras) that are easily attached to different structures – typically engaging a ‘pick and reposition’ sensor concept. A particular feature of the proposed system would be the availability of relatively low cost of individual sensing devices; to a level at which they can, if desired, be treated as disposable units. One of the most expensive and least reliable subsystems of the robotic agent is its propulsion mechanism. The mobility of the RtIOP device would depend on its acceptance by and cooperation with, the construction workforce. This is important, as pick and reposition requests will need to 'be moved' in relation to data capture mechanisms, which would be signalled audio-visually (e.g. by flashing LED). A key requirement here would therefore be for a worker to physically reposition the (signalling) unit. For instance, by clipping it to an appropriate safe structural component. Worker input would also extend to include simple repositioning tasks as required. The RtIOP system would therefore require operatives to be trained accordingly in order facilitate this interchange.

From a sensor perspective, each sensor unit is able to estimate its own position with respect to the construction site topology and the target work activity; thereby being able to plan the optimal trajectories needed reach its final destination in a finite number of 'pick and reposition' steps. Given this, the key enabler here is the low cost technology needed to making this a possibility, using for example a combination of existing proprietary ('off the shelf') GPS systems and SfM [Tao and Matuszewski, 2013; Tao *et al.*, 2013]; combined with Simultaneous Localisation and Mapping (SLAM) (Davidson *et al.*, 2007) computer vision algorithms.

Another but more expensive option would be to manage sensors' positional arrangements with the help of autonomous UAVs. This will engage pick and repositioning agents – to send out signals, indicating when a change of position is required. UAVs could then reposition sensors as and when prompted by the system. A set of software agents would address multiple data analysis tasks, including: vision based object recognition for non-obtrusive inventory; tracking and action recognition for onsite personnel management; and site map building (using an intelligent SLAM algorithm) for construction progress monitoring.

6. Conclusion

This study was motivated by the need for automated project monitoring and control systems for optimisation of day-to-day activities within AEC projects. This paper presented a review of the state of the art technologies that typically facilitate systematic project monitoring within the AEC domains. In order to address the issues (challenges) identified with existing systems, a proposed conceptual model was presented for discussion. This relies on the optimal use of artificial intelligence, cybernetics, and complex adaptive systems. The RtIOP model is supported by advanced intelligent agents; where the proposed platform can actively, autonomously and seamlessly manage intelligent agents (cameras, RFID scanners, remote sensors, etc.) in order to identify, report and document 'high risk' defect areas or activities.

The findings underpin a new ontological model that complements ongoing development of a dynamic, self-organised sensor (agent) network, for capturing and reporting real-time site data. As such, RtIOP is a 'stepping stone' for the advancement of automated project monitoring and control systems – using independent intelligent agents and sensory and computational support to perform complicated (previously manual) tasks. It is proffered that this solution can help deliver the three central tenets of project time, cost and quality.

Investigation of Relined Rehabilitated Piping in Residential Buildings

Parastou Kharazmi and Folke Bjork

Building Technology, Civil and Architecture Engineering, KTH Royal Institute of Technology, Stockholm, Sweden
Email: Kharazmi@kth.se

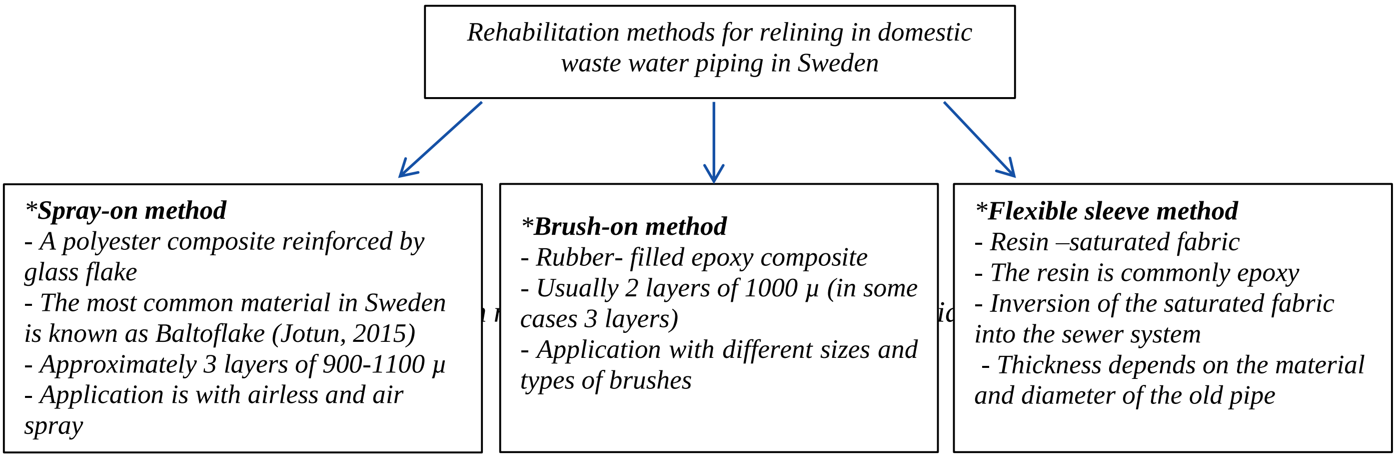
Abstract

In this paper rehabilitation methods for piping systems by relining in Sweden are reviewed. The paper also includes analyzing relined pipes which have been in the field between one to ten years to evaluate the quality and performance of the relining as well as typical problems which can occur. The investigated samples were sent to the laboratory for investigation and since they were not randomly taken out, the notations in this study should not be an indication of relining performance in general. However it can be said with certainty that improvement in technology is needed which is the reason of our study.

Keywords- Building, Pipe, Rehabilitation, Relining, Sewer

1. Introduction

Aging of water and waste water pipelines is a growing problem. Replacing of pipes in the traditional way is costly, disturbs local environment and is time consuming. These challenges have led to finding other types of renovation solutions such as rehabilitation with relining. In the relining technique, a new polymer pipe forms inside the old pipe without the need for taking the old pipe out. The use of relining methods and materials is increasing in Nordic countries, also in Sweden, due to the fact that water piping systems are getting old. Renovation by relining is faster and considerably cheaper compared to replacement of the old pipes. Flow chart 1 describes the three most common relining methods in Sweden.



One relining company, has introduced another technique with is called hybrid where both flexible sleeve and brush-on method are used to reline the host pipe. Different types of relining which are used in Sweden can be also classified and known as non-structural, semi-structural or fully-structural (AWWA, 2014), (Kharazmi, Björk, 2016).

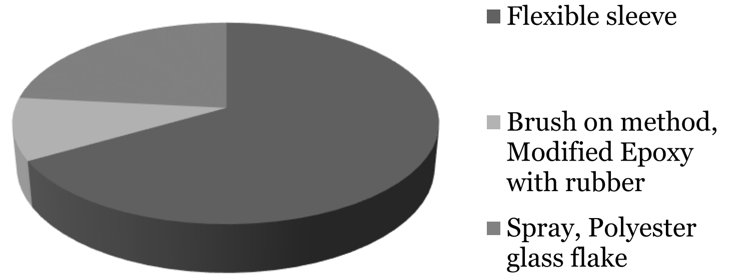


Figure 1 – Distribution of the three main relining application methods between relining companies in Sweden (2013)

Table 1- Pictures of pipe inspection by closed-circuit television

		
Figure 2-Closed-circuit television (CCTV) for inspection of the interior side of the water pipe and to evaluate condition of the host pipe (Proline, 2013)	*Figure 3- Application of the epoxy relining by brush-on method and controlling the procedure by camera(known as Dakki method in Sweden)*	*Figure 4-Closed-circuit television (CCTV) inspecting the interior of the pipe after application of the relining to evaluate condition of applied relining (Proline, 2013)*

Closed-circuit television (CCTV) is usually the method to inspect the interior of the water pipe and to evaluate quality of the installed pipe. The main reasons of inspecting the pipe are first, to evaluate the degree of cleaning and the required preparation for the existing pipe before starting the lining application, to detect any structural problems such as cracks, holes, leakage and also to check the pipe bends that can affect cleaning. The basic principle of CCTV inspection is that a television camera, together with a light source, is mounted on a tractor or skid which is pulled or propelled through the sewer from one manhole to the next. The camera transmits pictures by cable to a monitor (Ian G, 1997). To remove corrosion and standing water before application or installation of the relining, cleaning is required. The cleaning method is usually mechanical using a steel rod, which is called Drag Scrapers (Najafi, 2010). Based on recommendation by a manufacturer for the polyester composite (Jotun, 2016) all surfaces should be clean, dry and free from contamination. The surface should be assessed and treated in accordance with ISO 8504. Adequate drying time is related to the substrate temperature and the air circulation. For example based on the manufacturer's (Jotun) specification data, for the polyester Baltoflake, the temperature of the substrate should be at least 3°C above the dew point of the air to reach a good curing degree.

Although relining has been used in Sweden around 30 years, studying of the old relined pipes which have been taken out from the field, show improvement is needed, particularly regarding monitoring the quality of final products. Critical investigation of the quality level and studying the performance of different relining materials will create a basis for well-founded advices and recommendations. Moreover more investigation such as this ongoing study will provide better understanding regarding advantages and limitations of relining in comparison to a traditional replacement of the piping in residential buildings.

2. Performance of relined pipe with polyester and epoxy composites

Relining as a renovation technique is expected to perform well during a longer time. Therefore, it is promising to investigate the quality of common materials and techniques over time. To study the performance of relining, a study has been carried out on 11 relined pipes (as listed in Table 2) which have been in the field in different parts of Sweden. Different analyses were used to evaluate the quality of the installation and materials performance and in this paper the visual inspection, thickness measurement and materil comparison with FTIR spectroscopy will be discussed. Samples numbered from 1 to 6 were relined with rubber modified epoxy material applied by brushing method and samples 7 to 11 had relining material based on reinforced polyester with glass flake and applied with spray-on technique. Table 3 shows a cutted piece of each sample and provides a short summary of notification from visual inspection. The names of the relining companies for each sample will not be mentioned but the related information about each sample such as the applied material and technique, the time that they have been installed in practice and defects seen in visual inspection will be discussed.

Table 2- Samples description

Sample	*Type of relining material*	*Application method*	*Approximate time in service after relining*
1	*Epoxy based composite (Rubber filled)*	*Brush-on*	*6 years (2005-2011)*
2	*Epoxy based composite(Rubber filled)*	*Brush-on*	*6 years (2005-2011)*
3	*Epoxy based composite(Rubber filled)*	*Brush-on*	*10 years (2001-2011)*
4	*Epoxy based composite (Rubber filled)*	*Brush-on*	*14 days (2009)*
5	*Epoxy based composite(Rubber filled)*	*Brush-on*	*3 years (2008-2011)*
6	*Epoxy based composite(Rubber filled)*	*Brush-on*	*4 years (2007-2011)*
7	*Polyester based composite (reinforced with glass flake, known as baltoflake)*	*Spray-on*	*3 years (2008-2011)*
8	*Polyester glass flake(reinforced with glass flake ,known as baltoflake)*	*Spray-on*	*7 days (2010)*
9	*Polyester glass flake(reinforced with glass flake, known as baltoflake)*	*Spray-on*	*3 years (2008-2011)*
10	*Polyester glass flake(reinforced with glass flake, known as baltoflake)*	*Spray-on*	*2 years (2009-2011)*
11	*Polyester glass flake (reinforced with glass flake, known as baltoflake)*	*Spray-on*	*3 years (2008-2011)*

Table 3- Relined pipe which have been installed in the field

	*Sample 1- A relined pipe with rubber modified epoxy composite applied with brush-on method. The approximate time in service after relining has been 6 years.* *As can be seen, relining has been unevenly applied. Cracks could be seen and corrosion between lining and the host pipe can easily be detected.*
	*Sample 2- A relined pipe with rubber modified epoxy composite applied with brush-on method. The approximate time in service after relining has been 6 years.* *Corrosion and naked spots without any coverage with epoxy layer can be seen.*
	*Sample 3- A relined pipe with rubber modified epoxy and applied with brush-on method. The approximate time in service after relining has been 10 years.* *Uneven application of relining can easily be seen. Lining film was loose which could easily be separated in the edge of cutted pipe and heavy corrosion was spread through the relined pipe*
	*Sample 4- A relined pipe with rubber modified epoxy and applied with brush-on method. Approximate time in service after relining has been 14 days.* *The relined pipe was taken out only after 2 weeks because of the fail in application.*

	*Sample 5- A relined pipe with rubber modified epoxy and applied with brush-on method. Approximate time in service after relining has been 3 years.* *Besides air bubble which could be seen randomly on the outside of the film, no major defect can be detected.*
	*Sample 6- A relined pipe with rubber modified epoxy applied with brush-on method. Approximate time in service after relining has been 4 years.* *Sample had uniform film application without any major defect.*
	*Sample 7- A relined pipe with polyester baltoflake applied with spray method. Approximate time in service after relining has been 3 years.* *The lining was not applied in totally uniform layer. After cutting the piece of the relined pipe, the lining layer came off totally showing heavily corroded substrate surface of the original pipe.*
	*Sample 8- A relined pipe with polyester baltoflake applied with spray method. Approximate time in service after relining has been 7 days.* *Pipeline was taken out shortly after relining due to fail in rehabilitation. Uneven film and thickness variation can easily be seen.*

	*Sample 9- A relined pipe with polyester baltoflake applied with spray method. Approximate time in service after relining has been 3 years.* *Relining has formed a uniform film without major defect while a thin layer of corrosion between relining and host pipe can be seen.*
	*Sample 10- A relined pipe with Polyester baltoflake applied with spray method. Approximate time in service after relining has been 2 years.* *Relining has formed a uniform film without major defect but small cracks can be seen in a close inspection.*
	*Sample 11- A relined pipe with Polyester baltoflake applied with spray method. Approximate time in service after relining has been 3 years.* *Relining has formed a uniform film without major defect but small cracks can be seen in a close inspection.*

2.1. Thickness evaluation

According to the manufacturer of the relining materials (Jotun, 2015), also information provided by relining companies (e.g. proline, Dakki), lining with rubber modified epoxy (brushing method) and polyester based material (spray-on technique) shall be produced to have nominal thickness of 2 and 3mm respectively. Circumferential thickness measurements were carried out using a digital caliper with 10 measurements with 5 measurements from each edge of relined sample pipes. The results are shown in Figure 5 for the pipes relined with epoxy based relining applied with brushing and in Figure 6 for the pipes relined with polyester based relining material and spray technique.

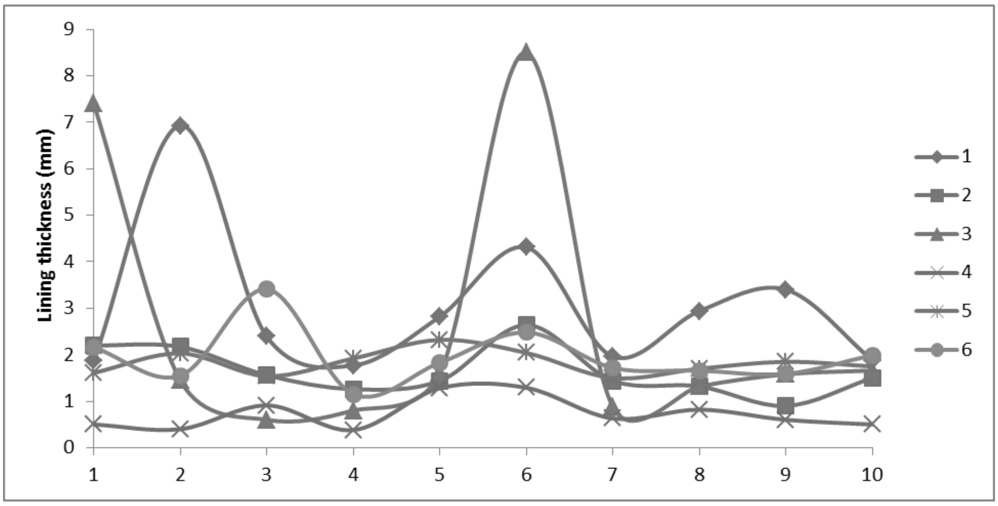

Figure 5: Circumferential thickness measurements for sample 1 to 6

In relining application, a uniform thickness application of the lining material should be applied all around the pipe for the material to be able to perform as expected; too much or too little material, causing very thin or very thick layers, remaining uncoated spots or forming sag, all are defects leading to poor performance of the relining. As it can be seen in Figure 5, sample 3 (which is the oldest sample) showed the highest variation in thickness. This is also possible to see in visual inspection and in the picture in table 2.

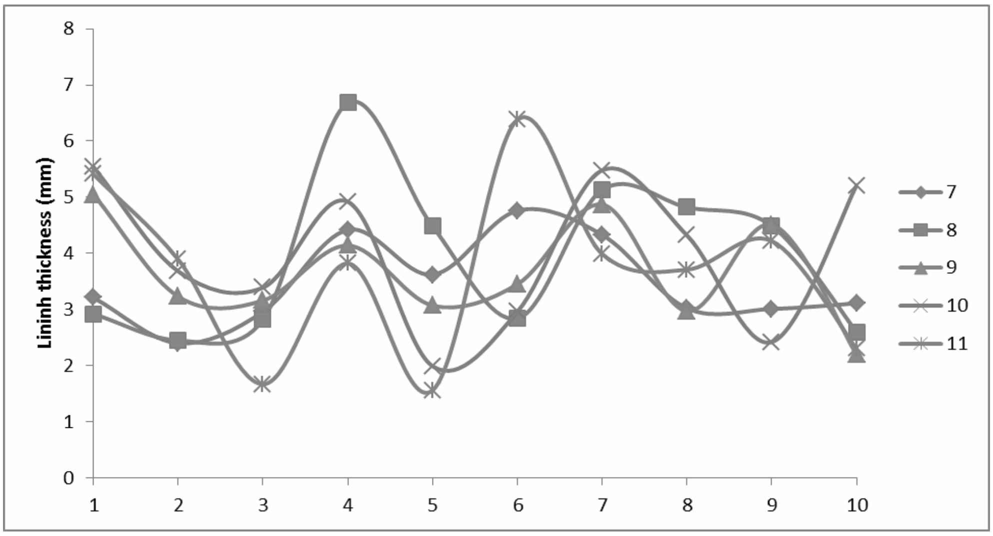

Figure 6- Circumferential thickness measurements for sample 7-11

Figure 5 shows that sample number 4 has the lowest thickness average and it can be seen from figure 6 that sample number 8 has a very uneven film thickness. These two samples have been taken out due to failure of the system and poor relining application.

2.2. Fourier transform infrared spectroscopy (FTIR)

FTIR spectroscopy was used to see if there is significant difference between the materials that have been used by different relining companies in each technique. The spectra were recorded from 400 to 6000 cm^{-1} using a Perkin Elmer FTIR instrument with scan number and resolution of 4 and 4 cm^{-1} in order. Figure 7 shows the FTIR spectra for the samples relined with epoxy based relining materials and Figure 8 shows FTIR spectra of relined samples with polyester based relining material.

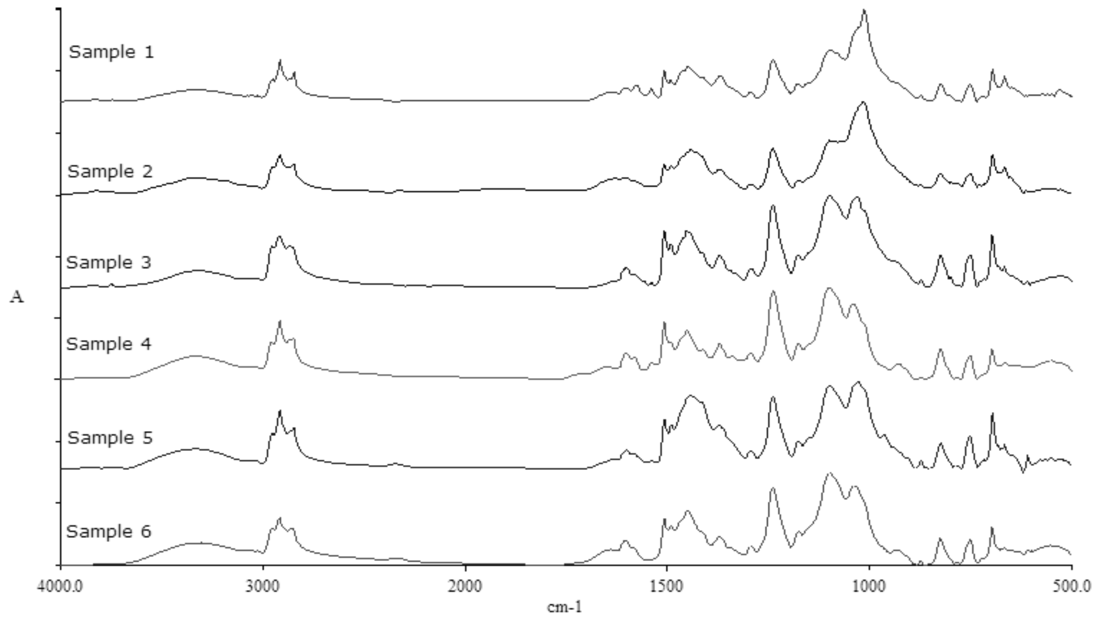

Figure 7- Normalized FTIR spectra for samples 1, 2, 3, 4, 5, and 6 (Epoxy based relining material)

Comparison of FTIR spectra shows that molecular structures of the materials which have been used in different projects are not the same. As it can be seen in the changes in spectra at 1100 cm–1, sample 1 and 2 are not similar to 3, 4, 5 and 6. This indicates that installation companies do not use the exact same material in brush-on method.

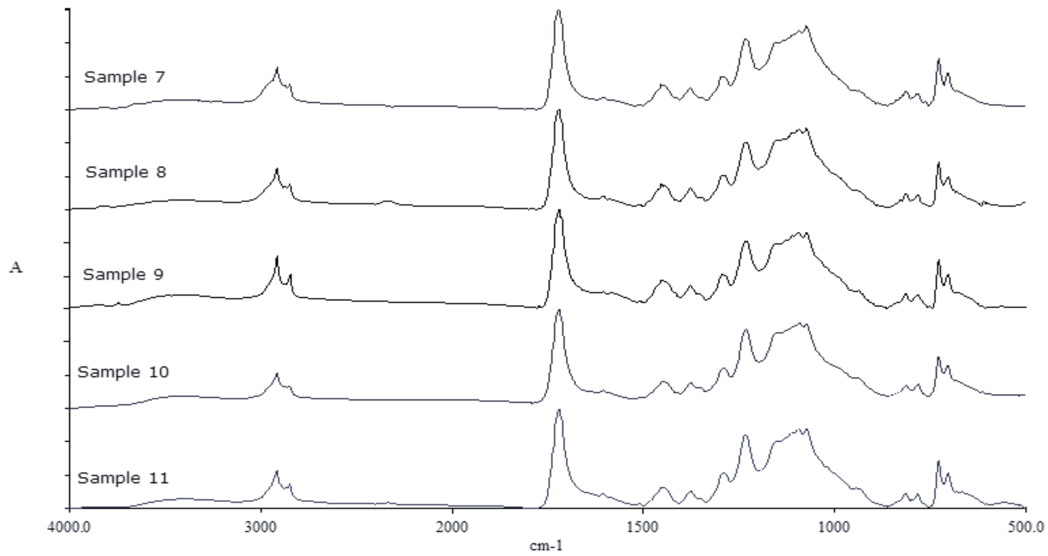

Figure 8- Normalized FTIR spectra for samples 7, 8, 9, 10 and 11 (Polyester based relining material)

FTIR spectra showed that molecular structures of the materials which have been used for sample 7 to 11 are similar indicating the same formulation/material that have been used in the different projects (more likely all have provided material so called Baltoflake).

3. Discussion

The uneven relining layer in Sample 1 can be due to a wrong viscosity of the composite in liquid state and before application. This can cause sagging, as can be seen in picture of sample 1, especially in gravity sewers which are majority of sewers in residential buildings. The existence of corrosion between liner and host pipe can be because of improper cleaning. In sample 2, relining was applied in a thinner layer than normal and this was the reason for inadequate coverage of the film, leaving some spots uncoated and consequently causing corrosion. Sample 3 shows uneven film formation of relining which was a cause of fail after application.

The reason for getting a loose lining layer can be mainly due to insufficient cleaning before application of relining. Sample 4 was taken out only two weeks after application due to poor application of relining. The layer of the applied film was very thin and the other problem was the material of the host pipe. A PVC pipe, as the original pipe, needs more consideration regarding preparation of the host pipe and before application of relining to secure adequate adhesion between lining layer and the host pipe. The air bubbles which can be seen in sample 5 can be due to inadequate mixture of the resin and hardener. Loose lining and corroded surface of the pipe in sample 7 can be again because of insufficient cleaning and poor preparation of the host pipe before relining application. The uneven film application in sample 8 can be due to the fail in proper preparation of the coating composite in liquid phase and before application. Uniform film application and good adhesion in sample 10 and 11 is mainly due to proper cleaning of the host pipe.

The investigation is highlighting the importance of proper cleaning and preparation before relining application. The other repeated result was a fail in applying a uniform and adequate film using lining material. Both of these defects are possible to prevent with enough attention to the quality of application.

Thickness measurements indicated that circumferential lining thickness for spray-on technique was more consistent compared to the brushing method in those samples which were studied here.

The FTIR analysis showed that materials used in Swedish market differ from some companies compare to others. This difference more likely will not cause any problem as long as the quality of the provided material is high enough. However it must be checked, for example with comparison of the purchased new batch of material with an accepted high quality sample as the reference.

It is worth mentioning that theses samples were not randomly taken out from different relining projects, therefore cannot be an indication of the quality performance of the relining techniques in general.

4. Conclusion

The investigation on the old relining samples taken from the field showed that developing a detailed quality control plan for each relining technique would provide more consistent quality between installation companies and manufacturers which are active in the field. The provision of the quality control requirements should be higher in different steps, such as inspection of the host pipe, cleaning, application and curing. Moreover choosing and applying the right material and giving adequate curing time and conditions can lead to a higher quality of the final result. Thickness measurements in this study indicated that circumferential lining thickness for both spray-on technique and brushing technique can be improved. It should be noted that samples discussed in this paper were not randomly taken out from different relining projects, therefore cannot be an indication of the quality performance of the relining techniques in general.
Studying the old relined pipes which have been in the field and in real conditions contributes greatly to a better understanding of the materials and techniques, limitations and advantages of this type of rehabilitation compare to the replacement of the pipelines and will help towards providing practical recommendation in close future.

Research on the Air Quality in the Classroom with Fresh Air Systems

Yan Huang, Xin Zhou, Li Minwen, Qiang Xu and Jingguang Li

Shanghai Research Institute of Building Sciences (Group) Co.Ltd, China
Email: lijingguang@vip.sina.com

Abstract

Natural ventilation is generally used in classrooms in China, though such ventilation strategy could not ensure good indoor air quality all the time. In order to establish healthy and comfortable air environment in the classroom, this study installed fresh air system (FAS) and analyzed the relationships between the fresh air rate and $PM_{2.5}$ and CO_2 distributions. On-site measurement shows that after turning on the FAS, the fresh air rate raised from 2.4 m^3/h per person to 6.1 m^3/h per person, and the indoor $PM_{2.5}$ concentration decreased from 40 μg/m^3 to 18 μg/m^3. However, the CO_2 concentration still exceeded 2000 ppm, as the actual airflow rate of the FAS was 43.6% of its' rated airflow rate. Through calculation, this study recommended the minimum fresh air rate in the classroom should be 24.0 m^3/h per person to ensure the CO_2 concentration less the 1000 ppm. Furthermore, the economic analysis indicated that the FAS we chosen had both low initial invest and operating cost.

Keywords: Fresh air rate, Carbon-dioxide, $PM_{2.5}$

1. INTRODUCTION

Indoor air quality (IAQ) is highly related to student's health, comfort and study efficiency in the classroom. With the increase of the ventilation rate from 2.5 m^3/h per person to 19 m^3/h per person, the study performance would increase 10% (Kaneko, et al., 2007). A 1000 ppm increase in ΔCO_2(indoor minus outdoor CO_2 concentration) was associated with 10~20% increase in student absence (Shendell et al., 2004).

However, the IAQ is not so satisfy in Chinese classrooms nowadays. The CO_2 concentration was over 1000 ppm in 89.7% of the measured classrooms (Liu et al., 2005), In Deng's (2007) study, the CO_2 concentration in the classroom was 3800 ppm, with the fresh air rate of 0.29 ACH. Zhu et al. (2012) monitored $PM_{2.5}$ concentration of 114 classrooms in Shenzhen, China, and found the average $PM_{2.5}$ concentration was 71 μg/m^3, which was much higher than the limited level in *Ambient Air Quality Standards* (*GB3095-2012, Chinese standard,* 35 μg/m^3).

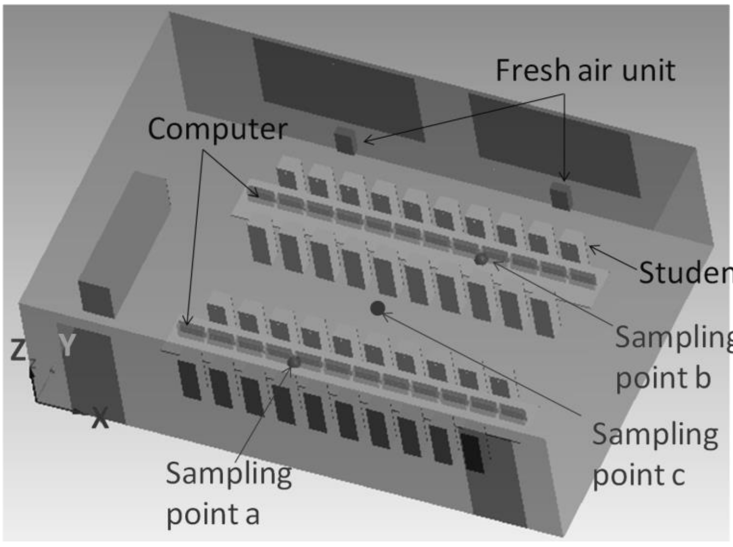
Natural ventilation is generally adopted in the classroom in China. Such method highly depends on the outdoor air quality. Due to the heavy haze resent years in China, it is recommended to close the window to prevent the outdoor contaminant spreading to indoor space. On the other hand, closed window leads insufficient fresh air, causing high CO_2 concentration and odors. In order to establish healthy and comfortable indoor air environment in the classroom, this study installed fresh air system and analyzed the relationship between the fresh air rate and $PM_{2.5}$ and CO_2 distributions.

2. METHODOLOGIES

2.1 Experimental method

This study installed the fresh air system (FAS) in a computer classroom of a middle school located in Shanghai, China. The classroom was 11.74 m in length, 7.97 m in width and 3.24 m in height (Figure 1). Ventilation rate, $PM_{2.5}$ and CO_2 concentration were measured in both cases of FAS on and off. There were 40 students in the classroom during the measurement.

(a)



(b)

Figure 1: The classroom configuration (a) used in the measurement (b) used in the model

Tracer gas decay method (Zhu, 2005) was adopted to measure the air change rate, and the tracer gas was Sulfur hexafluoride (SF_6). INNOVA 1303 and 1312 were used to test the SF_6 concentration. Dusttrak8530 aerosol monitor was used for $PM_{2.5}$ concentration measurement, with the sampling frequency of 1 min. AZ7798 CO_2 datalogger was used for CO_2 concentration measurement, with the sampling frequency of 2 min. As shown in Figure 1 (b), The sampling points for CO_2 concentration were placed on the desk, which were close to the breathing zone of students. The sampling point for $PM_{2.5}$ concentration was in the middle of the classroom.

2.2 Calculational method

The indoor $PM_{2.5}$ concentration was calculated via the following mass conservation equation:

$$V\frac{\mathrm{d}C}{d\tau} = G + C_{out}Q_l\sigma + C_{out}(1-\eta)Q_i - CQ_o - C\times CADR \quad (1)$$

where C is the indoor $PM_{2.5}$ concentration at τ time (μg/m^3), C_{out} the outdoor concentration (μg/m^3), G the indoor $PM_{2.5}$ emission rate (μg/h), σ the penetration coefficient, η the primary filtration efficiency of the fresh air system, Q_l the air leakage rate (m^3/h), Q_i the supply air rate (m^3/h), Q_o the exhaust air rate (m^3/h), $CADR$ the clean air delivery rate (m^3/h), V the room volume (m^3), τ the time (h).

Considering steady condition, this study set $\frac{\mathrm{d}C}{dt} = 0$. Via measurement, the $PM_{2.5}$ concentration at inlet was zero and there was no air cleaner in the room. Then Equation (1) was simplified as:

$$G + C_{out}Q_l\sigma_i - CQ_o = 0 \quad (2)$$

Moreover, this study also simulated the indoor CO_2 concentration distribution by Computational Fluid Dynamics (CFD). We discretized the classroom space into 1.08 million cells via Ansys Workbench 2014. Hexahedral mesh was used, with the skewness less than 0.97. All the boundary conditions were measured and input into Ansys Fluent 14.0. Re-Normalization Group k-ε (RNG k-ε) model was selected to approximate the Navier-Stokes equations. As for numerical schemes, this study used the SIMPLE algorithm to couple the pressure and velocity. The PRESTO! scheme was used for pressure discretization and the second-order upwind scheme for all the other variables. The solutions were considered to be converged when the sum of the normalized residuals for all the cells became less than 10^{-6} for energy and 10^{-3} for all other variables (Fluent, 2011)

3. Results

3.1 Ventilation rate

Figure 2 depicts the designed and measured fresh air rate with the fresh air system (FAS). When the windows and FAS were both closed, the fresh air rate in the classroom was 96.4 m^3/h, namely 2.4 m^3/h per person. After using the FAS, the fresh air rate increased to 244.0 m^3/h, namely 6.1 m^3/h per person. According to *Code for Design of School* (*GB50099 -2011,Chinese standard*), the minimum fresh air rate in the middle school should be 14 m^3/h per person, so that the designed ventilation rate should be 560 m^3/h (as for 40 person). However, the actual airflow rate of the FAS was 43.6% of its' rated value. The reason for such deviation between the rated and actual airflow rate was that the FAS was rated at laboratory condition, which was quite different with the actual operating condition. Under the operating condition, the fresh air unit external static pressure was not the same as the value when it was tested in laboratory, so the actual supply air rate was not its' rated airflow rate. Therefore, this study suggested the FAS rating test condition should be more close to its' actual operating condition.

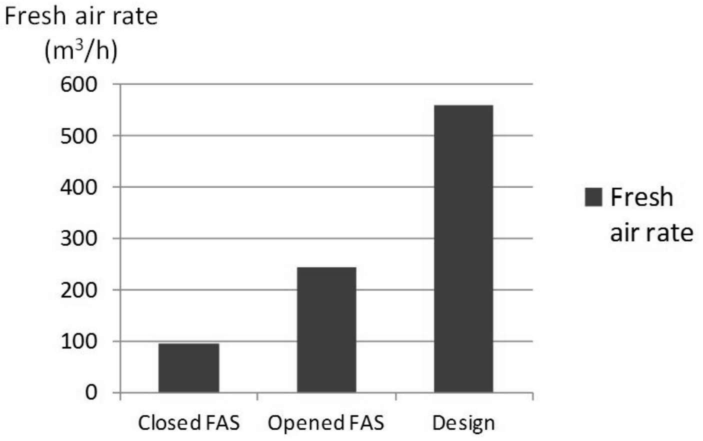


Figure 2: The designed and measured fresh air rate with the fresh air system(FAS)

3.2 CO_2 concentration

Figure 3 compares the CO_2 concentration in the classroom during the school day and weekend with natural ventilation. When the windows and FAS were both closed, the CO_2 concentration was approximately 3200 ppm during the class, while it was around 400 ppm at weekend. According to *Indoor Air Quality Standard* (*GB/T 18883, Chinese standard*), the indoor CO_2 concentration should be less than 1000 ppm. However, the CO_2 concentration in the classroom was much higher than the standard limit with natural ventilation.

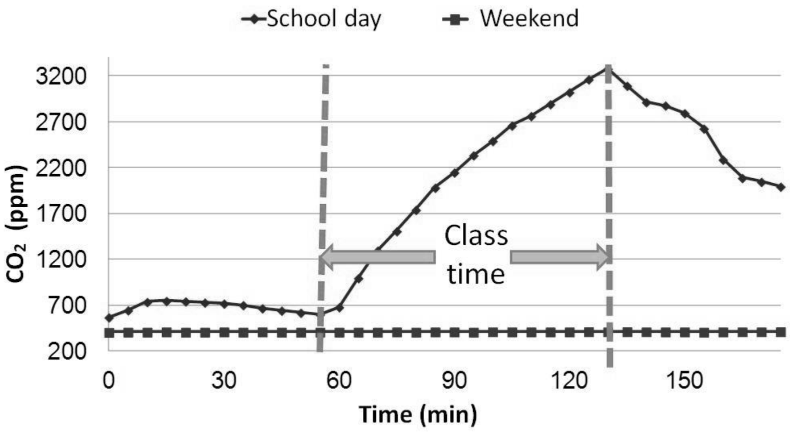

Figure 3: Indoor CO_2 concentration with natural ventilation

Figure 4 shows the CO_2 concentration from 9:45 to 14:00 at sampling point a. The CO_2 concentration at sampling point b was also monitored and similar results could be found. At stage 1, the FAS was off, so the CO_2 concentration rose from 848 ppm to 1927 ppm at sampling point a, and from 802 ppm to 2063 ppm at sample b. During the break (stage 2), the CO_2 concentration reached the peak at first, and then it started to decrease as the doors were opened and some students went out of the classroom, which lead more fresh air rate and fewer CO_2 sources. At stage 3, the FAS was turned on at the beginning of the second class. Comparing with stage 1, the CO_2 concentration growth rate declined. However, the CO_2 concentration still exceeded 2000 ppm at the end of stage 3. As mentioned in section 3.1, the actual supply air rate was much less than the designed value, causing the indoor CO_2 concentration exceeded the required value in the standard.

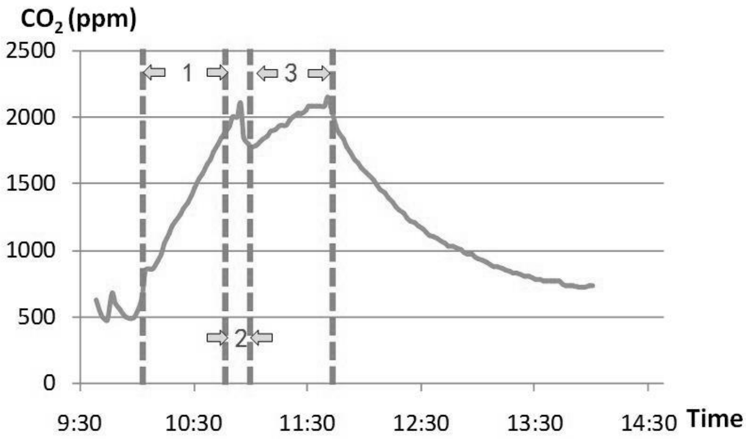

Figure 4: CO_2 concentration at sampling point a (stage 1: the class time with closed FAS; stage 2: the break; stage 3: the class time with opened FAS)

In addition, CFD was employed to simulate the indoor air and CO_2 distributions. As seen in Figure 5, when the fresh air rate increased from 244.0 m^3/h (6.1 m^3/h per person) to 960.0 m^3/h (24 m^3/h per person), the CO_2 concentration decreased from 2024 ppm and 2191 ppm to 908 ppm and 762 ppm at sampling point a and b respectively.

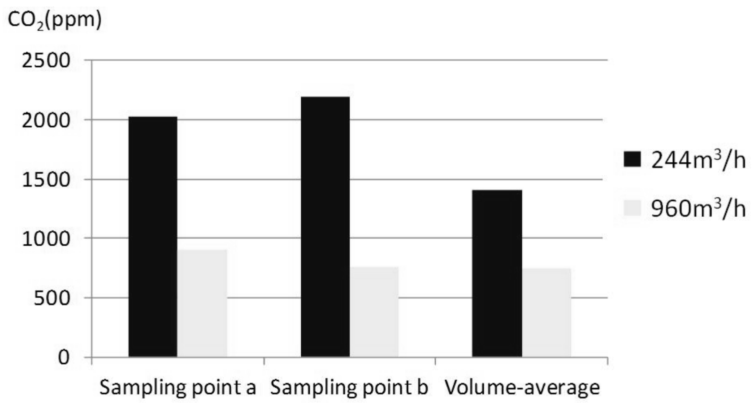

Figure 5: The CFD simulated CO_2 concentration at sampling point a, b and the volume-averaged concentration with different fresh air rate

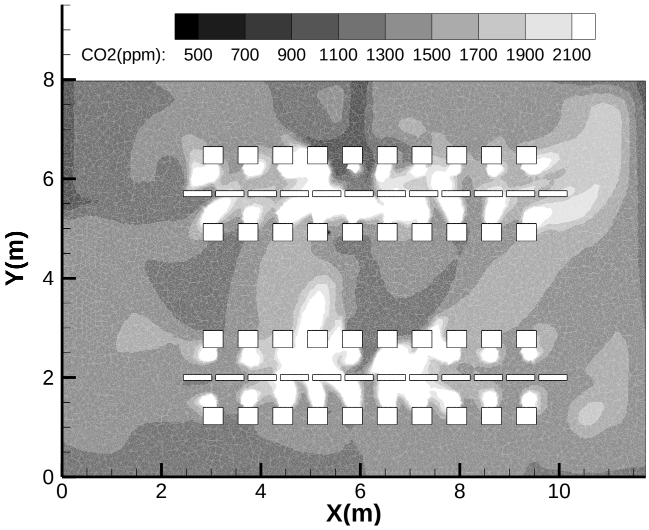
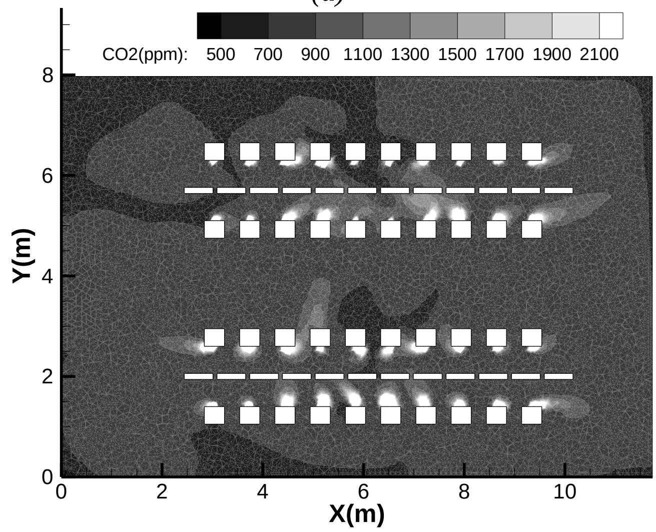
Figure 6 displays the CO_2 distribution at Z=1.1 m in the classroom. When the fresh air rate was 244 m^3/h, the CO_2 concentration around students was higher than 1300 ppm. When the fresh air rate was 960 m^3/h, the CO_2 concentration in most space was lower than 900 ppm. With the increase of fresh air rate, the volume-average CO_2 concentration decreased from 1409 ppm to 750 ppm， which could meet the requirement of the *Indoor Air Quality Standard* (*GB/T 18883*, *Chinese standard*).



(a)



(b)

Figure 6: The CFD simulated CO_2 distribution at Z=1.1 m in the classroom (a) with fresh air rate of 244 m^3/h (b) with fresh air rate of 960 m^3/h

3.3 $PM_{2.5}$ concentration

This study also analyzed the $PM_{2.5}$ concentration in the classroom. We monitored the indoor and outdoor $PM_{2.5}$ concentration simultaneously. As shown in Figure 7, when using natural ventilation, the $PM_{2.5}$ indoor/outdoor (I/O) ratio was 0.50~0.70 with the closed windows, while it rose to 0.89 in 30 min after opening the windows. Thus, natural ventilation could not prevent outdoor $PM_{2.5}$ spreading to indoor spaces.

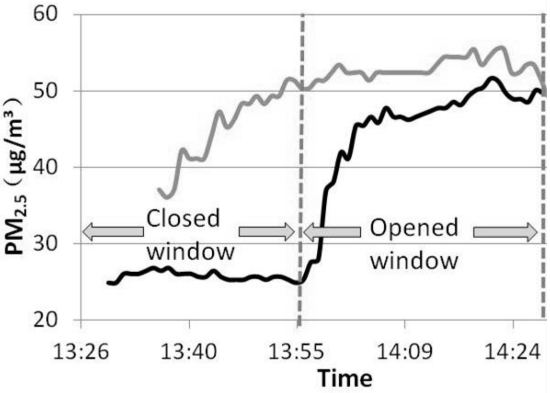


Figure 7: Indoor and outdoor $PM_{2.5}$ concentration with natural ventilation

When using the FAS, the indoor $PM_{2.5}$ concentration decreased from 40 μg/m^3 to 18 μg/m^3 and the I/O ratio decreased from 0.75 to 0.32, as shown in Figure 8.

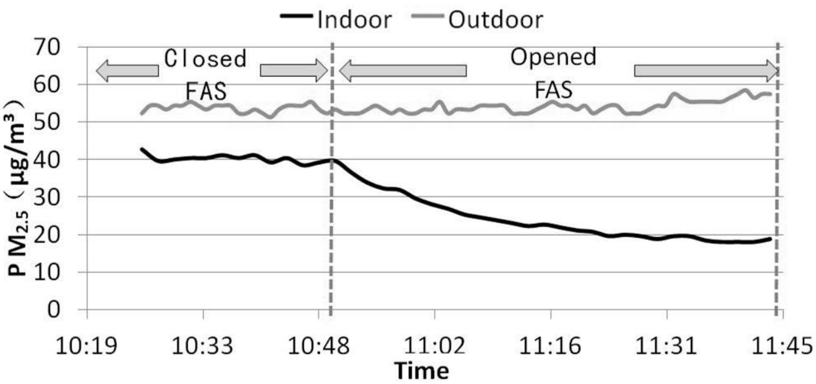

Figure 8: Indoor and outdoor $PM_{2.5}$ concentration with the FAS

Moreover, this study calculated the indoor $PM_{2.5}$ concentration via mass conservation equation. The main indoor $PM_{2.5}$ source was occupants. As Xu (1998) studied, the particles emission rate from occupants ranged from 2.2μg/m^3 (sit) to 3.0 μg/m^3 (wrist movement) for 40 persons. The outdoor $PM_{2.5}$ concentration was set as 54.1 μg/m^3 and the air leakage rate was 96.4 m^3/h based on measurement data. The calculated indoor $PM_{2.5}$ concentration was 19.4 μg/m^3～20.2 μg/m^3 via Equation (2) and the deviation between the calculated and measured results was -7.8%～-12.1%.

3.4 Economic analysis

The initial invest on the FAS was 8000 RMB. The operating cost depended on the operating time. This study set the operating time as 128 days (school days) per year and 8 h per day, whose daily-average outdoor $PM_{2.5}$ concentration exceeded 35 μg/m^3 (the requirement of *Ambient Air Quality Standard GB/T 3095)*. The outdoor $PM_{2.5}$ concentration data was acquired from Shanghai Environmental Monitoring Station. The rated power of the fresh air unit was 92 W and the electricity price was 1 RMB/kWh. Through calculation, the energy charge of the FAS was 94 RMB per year. Thus, the FAS had both acceptable initial invest and operating cost.

4. Conclusion

This study installed fresh air system (FAS) in the classroom to ensure healthy and comfortable indoor air environement. Both measurement and calcultion were used to analyze the relationship between the fresh air rate and $PM_{2.5}$ and CO_2 distributions. The following conclusions can be drawn:

1) The fresh air rate was 2.4 m^3/h per person in the classroom with closed windows. After using the FAS, it rose to 6.1 m^3/h per person. However, the actual airflow rate of the FAS was 43.6% of its' rated value, due to the deviation between the FAS rating test condition and the operating condition.

2) The indoor CO_2 concentration was approximately 3200 ppm during the class with closed windows. After using the FAS, the growth rate of the CO_2 concentration declined. However, the indoor CO_2 concentration still exceeded 2000 ppm, due to the insuffient supply air rate of the FAS. Through calculation, this study recommended the minimum fresh air rate in the classroom should be 24.0 m^3/h per person to ensure the CO_2 concentration less than 1000 ppm.

3) Natural ventilation could not prevent the outdoor contaminant spreading to indoor spaces. When using the FAS, the indoor $PM_{2.5}$ concentration decreased from 40 $\mu g/m^3$ to 18 $\mu g/m^3$ and the I/O ratio decreased from 0.75 to 0.32

4) The initial invest on the FAS was 8000 RMB and the energy charge was 94 RMB per year, which was economical acceptable.

An Investigation on Fire Hazard and Smoke Toxicity of Epoxy FRP Composites

Saeed Bakhtiyari, Leila Taghiakbari and Masoud Jamali Ashtiani

Road, Housing & Urban Development Research Centre (BHRC), Iran
Email: bakhtiari@bhrc.ac.ir

Abstract

The fire performance of two types of fibre reinforced epoxy composites (GFRP and CFRP) was studied in bench-scale using cone calorimeter test method in two incident heat fluxes of 35kW/m^2 and 50kW/m^2. Ignitability, time to ignition, heat release rate, total heat release, smoke release parameters and Carbon monoxide production were measured and discussed. Both thermal and smoke toxicity hazard of the material was studied. The time to flashover in an assumed room lined with the tested FRP was predicted with using Conetools software. The obtained results showed that the tested FRP products had a dangerous behaviour in case of fire, so it could show a high contribution to fire growth due to the combustible nature of epoxy resin. The tests also showed that these kinds of resins have a low glass transition temperature, around (50-60) °C. Therefore, the mechanical strength (and strengthening potential) of the product might be critically reduced at first stages of a fire incident. This shows that a regular thermal barrier, which is typically used for protection of plastic foams against fire, may be not sufficient for this purpose for FRP composites and a higher level of fire protection may be needed for prevention of failure of the strengthened system. The performance of protected FRP composites with a type of mineral spray applied coatings is discussed in another article.

Keywords: FRP, fire hazard, reaction to fire, ignitability, smoke.

1. Introduction

One of the main concerns with using polymer composites is their performance in the case of fire. The reason is that the FRP materials are inherently flammable due to nature of its polymeric resin. Furthermore, typical polymer resins for FRPs for civil engineering applications typically have glass transition temperatures between 60°C to 80°C [1, 2]. Hence, it is necessary to assess their fire behaviour due to widespread structural applications including strengthening and retrofitting. For assessment of fire hazard of a material, measurement of its reaction to fire properties are needed, including ignitability, peak and average values of heat release rate (PHRR and Av.HRR), total heat release (THR), etc. Other important properties include smoke and yield of toxic gases especially carbon monoxide, which in turn affect on visibility and ability of people to escape from the building engaged in fire, i.e. on life safety aspects [3]. In this paper fire performance of the two types epoxy CFRP and GFRP composites is discussed. Reaction-to-fire properties of specimens including thermal, smoke and toxic gases were measured with ignitability and cone calorimeter tests. Then the fire hazard of the specimens were assessed, based on Petrella method, in which the flashover propensity (x parameter) is defined and used for this purpose, as is outlined in continue. Time to flashover (t_{fo}) was predicted based on cone calorimeter results by Conetools software.

2. Experimental

2.1 Materials

The samples were two kinds of epoxy/glass (GFRP) and epoxy/carbon composites (CFRP). The specimens were provided by the commercial sources. The reason for choosing these two FRP composites is that they are common for external reinforcement of concrete structures in Iran. The matrices of both FRP composites were epoxy resin and only their reinforcing fibres were different (glass and carbon fibres). The thicknesses of all samples were approximately 3 mm.

2.2 Test procedure

Ignitability fire test

The ignitability test was carried out according to ISO 11925-2, which specifies a method of test for determining the ignitability of vertically oriented test specimens when exposed to a small flame, either at the edge or the surface of the specimens. Flame spread and occurrence of burning particles and droplets are observed during the specified flame exposure. The six flat specimens shall be used with dimensions: 250mm × 90mm and maximum thickness 60mm. The flame is applied for 15s (test duration 20s) and 30s (test duration 60s). The test results can be used for assessing a classification according to EN 13501-1.

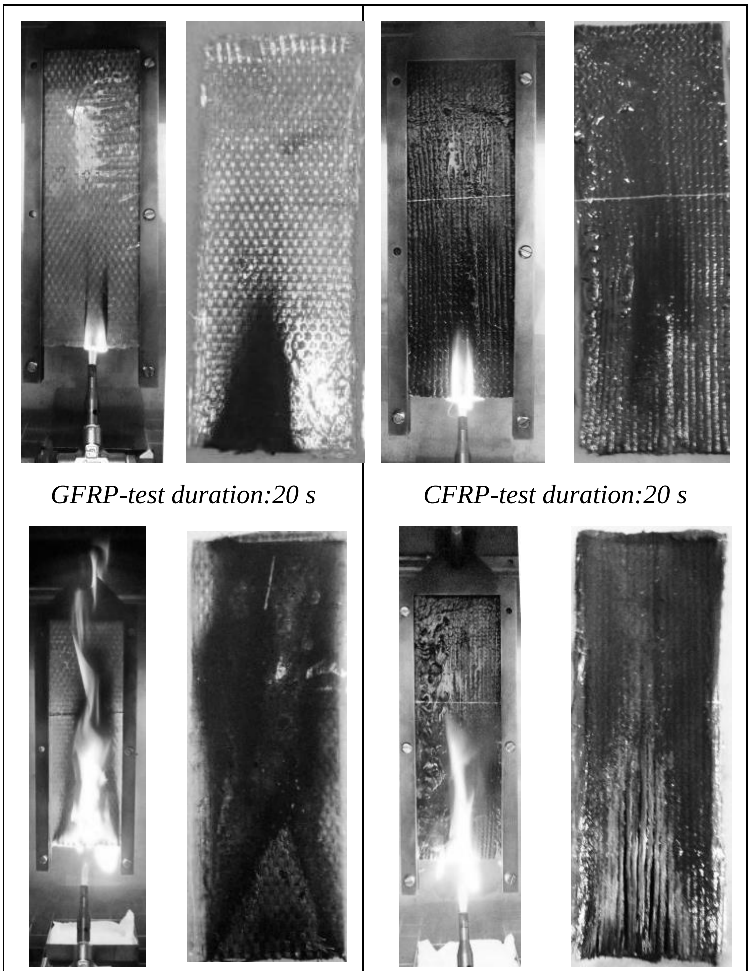
Cone calorimeter fire test

The bench-scale fire test was performed with cone calorimeter according to ISO 5660-1. The specimens were cut as 100 by 100 mm square samples. Two incident heat fluxes of 35kW/m^2 and 50kW/m^2 were set for evaluations. Three tests were carried out for each incident heat flux.

3. Discussion

3.1 Thermal aspects

At first a simple ignitability test were done on both samples. For both set of specimens, the flame tip did not reach the distance of 150mm during the test at 15s flame exposure. However, in contrary, when the tests were carried out at 30s flame exposure, the flame tip reached to a distance of 150mm before the end of the test duration. Thus, according to the test results and classification method of EN 13501-1, the tested FRP specimens met the reaction to fire class of E. Figure 1 shows the CFRP and GFRP specimens during the ignitability fire test.



GFRP-test duration:20 s | *CFRP-test duration:20 s*

GFRP-test duration:60 s | *CFRP-test duration:60 s*

Figure 1: GFRP and CFRP epoxy composites during ignitability fire test

Cone calorimeter tests were carried out at two radiation heat fluxes of 35kW/m^2 and 50kW/m^2. All of the specimens were ignited under these radiation heat fluxes in less than 1 min. The results showed a high flammability of tested materials. The PHRR values were high at both radiation levels (figure 2). In addition, TTI of the specimens were about 20s at 50kW/m^2 (table 1). The definitions of abbreviations are as following:

abbreviations	*Comment*	*abbreviations*	*Comment*
ρ (kg/m^3)	*Volumetric density*	*Av. SEA (m^2/kg)*	*Average of specific extinction area*
TTI (s)	*Time to ignition*	*TSR(-)*	*Total smoke released*

Mi (g)	*Initial mass*	t_{fo} *(s)*	*Time to flashover*
ML (g)	*Mass lost during the test*	*Peak CO (ppm)*	*Peak concentration of CO*
PHRR (kW/m^2)	*Peak of heat release rate*	*pk.COY (kg/ kg)*	*Peak yield of carbon monoxide*
THR (MJ/m^2)	*Total heat released*	*pk.CO2Y (kg/ kg)*	*Peak yield of carbon dioxide*
x=PHRR/TTI ($kW/m^2.s$)	*Flashover propensity*	*FED=pkCO/5000*	*Fractional effective dose*

Table 1: Reaction to fire thermal/smoke parameters in heat radiation levels 35kW/m^2 and 50kW/m^{2}in

Specimen / Parameters[1]	GFRP	CFRP	GFRP	CFRP
ρ	1230	872.5	1071	877.6
Heat flux	35 kW/m^2		50 kW/m^2	
Thermal parameters				
TTI	56	38	22	23
Mi[2]	41.0	26.4	34.7	27.8
ML[3]	16.9	18.7	18.5	20.9
PHRR	636.1	551.0	693.4	643.4
THR	59.1	52.7	49.3	54.9
x=PHRR/TTI	11.4	14.5	31.5	28
Smoke parameters				
Av. SEA	-	811.7	734.0	878.7
TSR	-	1723	1528	2090
Predicted time to flashover-conetools				
t_{fo}	-	-	81	74

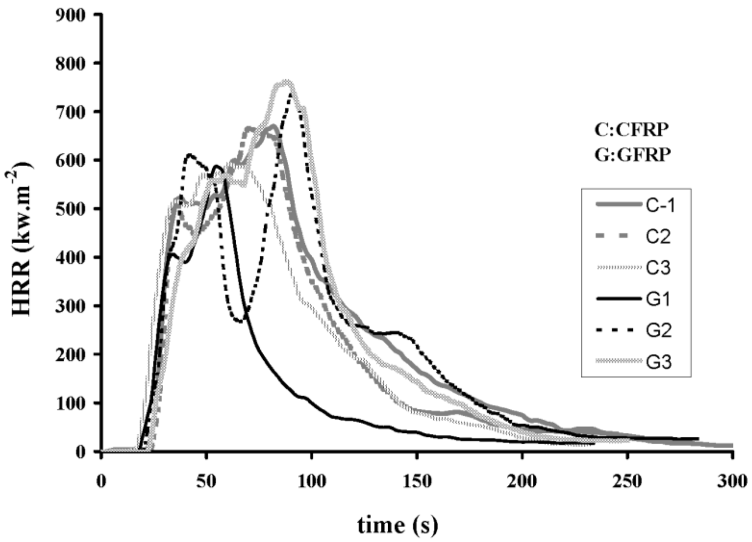


Figure 2: Heat release rates from GFRP and CFRP epoxy composites in heat flux 50kW/m²

The results shown in table 1 are the average values. Therefore, based on these results, these FRP materials would have a high contribution in growth of fire, if used without a protection layer. This shows that use of a protective layer for prevention of premature ignition and high contribution of materials in fire growth is necessary. Figure 3 shows the GFRP and CFRP specimens during cone calorimeter test in heat flux of $50kW/m^2$.

GFRP

CFRP

Figure 3: GFRP and CFRP epoxy composites during cone calorimeter fire test

The fire hazard of tested materials was analyzed with different methods. According to Petrella [4], the flashover propensity or x parameter is defined as ratio of PHR to TTI (in $kWm^{-2}s^{-1}$) and can be used for fire hazard classification of materials. In addition, he proposed a two-fold system consisting of the x parameter and total heat release (THR) for fire hazard evaluation, an attributed x parameter and THR to different fire hazard classes as following: x: 0.1-1.0 (low risk); 1.0-10 (intermediate risk); 10-100 (high risk) and THR: 0.1-1.0 (very low risk); 1.0-10 (low risk); 10-100 (intermediate risk); 100-1000 (high risk). Some researchers used this method for fire hazard assessment [5-6]. The x parameter of tested GFRP and CFRP specimens was calculated and compared with the method proposed by Petrella. The results are given in table 1 and as it can be seen both GFRP and CFRP showed high flashover propensities. An intermediate risk was acquired based on THR figures, which were in the range of 49-59 $MJ.m^{-2}$. Using test data from cone calorimeter, a time to flashover of 80s was acquired with conetools software for tested materials.

3.2 Smoke and toxic gases

The average specific extinction area (Av.SEA) and total smoke release (TSR) are reported. Attenuation of light (reducing incident intensity from I0 to I) by soot particles is proportional to the projection area (in m^2) of particles blocking the distance L (in m) between the light source and the receiver. SEA is a measure of this value normalized by the fuel mass [4]. Based on the values shown in table 1 this smoke parameter is relatively high.

The yields of toxic gases including carbon monoxide and carbon dioxide (COY and CO2Y) and the peak concentration of CO (pk[CO]) are given in table 2. CO concentration versus time is given in figure 4.

Table 2: toxicity aspects based on bench-scale cone calorimeter parameters in heat radiation level 50kW/m²

Specimen / *Parameters*	*GFRP*	*CFRP*
ρ	*1071*	*877.6*
Peak CO	*1153.4*	*888.3*
pk.COY × 100	*130*	*110*
pk.CO2Y × 100	*2440*	*2260*
FED=pkCO/5000	*0.23*	*0.18*

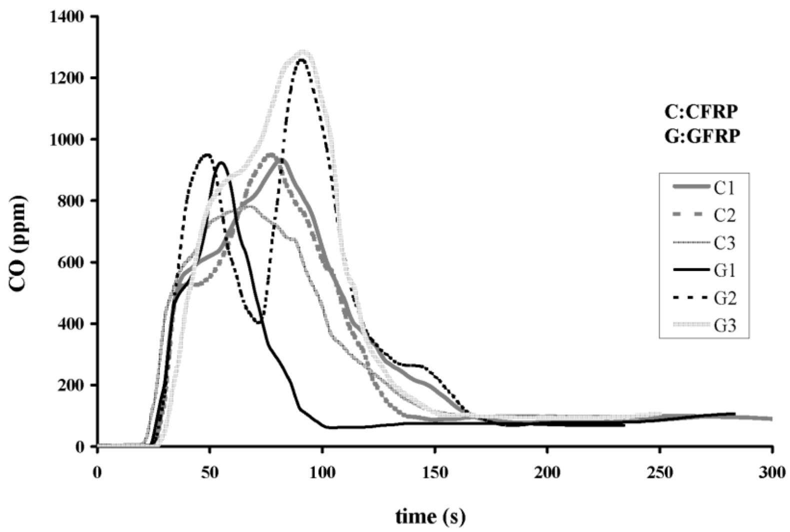

Figure 4: Carbon monoxide concentration of GFRP and CFRP epoxy composites in heat flux 50kW/m^2

It was observed that the value of pk[CO] was very high. It should be noted that the cone calorimeter is an open laboratory test and during the test about 24 lit/s fresh air is ventilated in the hood system. So the CO concentration is continuously diluted with the fresh air and it is not directly the CO concentration that can be expected in a real fire incident. In the other side, the integral of the area under curve of CO concentration might be a better index of the produced CO. As it can be seen from the figure 4, the CO concentrations of the tested materials were high.

A method of assessing toxic hazard in fire is fractional effective dose (FED). FED can be obtained from the ratio of the average concentration of a gaseous toxicant to its LC50 value [7]. Since CO and CO2 are measured in cone calorimeter and toxic potency LC50 for CO2 is much greater than LC50 for CO [8], FED was calculated [5] from pk[CO] in the cone calorimeter by:

$$\mathrm{FED} = \frac{\mathrm{pk}\,[\mathrm{CO}]}{5000}$$

The resulted FED was about 0.2 for tested specimens (table 2). Comparing with literature values for different materials [5] this can be taken as a relative high value. In the other side, as it was discussed in the above, the test is an open type with continues suction of fresh air. This is something again here that should be taken into account for interpretation of the results; and regarding this matter it can be said that the studied materials showed a high potential for producing toxic gases in case of fire, which is very important for life safety and evacuation of people from the building. Two factors including oxygen depletion and increasing of CO (and the other toxic gaseous) seriously affects survivability.

4. Conclusions

Fire behaviour of two types of fibre reinforced epoxy composites (CFRP and GFRP) was evaluated by reaction to fire tests including ignitability and cone calorimeter. Cone calorimeter tests were carried out in two different incidental heat fluxes of $35kW/m^2$ and $50kW/m^2$. Both FRPs Products showed relative dangerous behaviours in case of fire. They were highly flammable and their peak heat release rates were higher than $600kW/m^2$, which is a very high value.

Fire hazard assessments were done according to the method proposed by Petrella and also with use of Conetools software. The smoke and CO production of the materials were measured with cone calorimeter and then assessed using the related theories and methods. The results revealed that such FRP materials, used for external strengthening of concrete structures, are dangerous in case of fire, if they are used without a protective coating. In addition, the resin matrix would be rapidly molten, paralyzed and involved in combustion, if exposed to fire or high temperatures. So the mechanical strength of the system would be rapidly decreased and the system might be prematurely falls to a structural failure. Hence it is needed to protect the FRP system, due to both reaction-to-fire and fire resistance requirements. The results showed that high smoke and CO values from burning the FRPs. Furthermore, the obtained data revealed that there is a serious need for regulating the use of the FRP composite materials in building and other applications. Moreover, the study clearly shows the limitations of FRP composites applications should be determined based on the fire safety requirements in buildings especially widespread application for strengthening and rehabilitation of structures.

Risk Assessment Impact on Landfill Structures Design

Hannu Aurinko

Laatuinsinöörit Oy, Finland
Email: hannu.aurinko@laatuinsinoorit.fi

Abstract

The purpose of this research was to investigate environmental permits of landfills with respect to the appropriateness of risk assessments focusing on contaminant migration, structures capable to protect the environment, waste and leachate management and existing environmental impacts of landfills. The objective of the environmental permit procedure is to ensure that the landfill owner has prepared a plan to protect the landfill environment using the Best Available Technique (BAT) and specialists with sufficient expertise. The plan includes structures for the protection of the environment with the help of which the environment, groundwater, surface water and the climate can be protected on a sufficient protection level during the whole life-cycle of the landfill according to the laws and regulations in force.

The directive admits of possible exceptions to the structural requirements if the protection capability of the deviations can be demonstrated to be corresponding with the help of risk assessment. Landfills risk assessing methods typically focuses on structural dimensions and harmful substances flux instead of focusing on local circumstances in Finland.

Several development needs were found in the risk assessments of the environmental permit decisions. The risk analysis equations used in the decisions did not adequately take into account all the determining factors like waste prospects, total risk quantification or human delineated factors. Instead of focusing on crucial factors, the landfill environmental protection capability is simply expressed via technical factors like hydraulic conductivity.

In this paper, it could be shown, that using adequate risk assessment approaches the most essential environmental impacts can be taken into account by consideration of contaminant transport mechanisms, leachate effects, and artificial landfill structures. The developed structural risk analysing (SRA) method shows, that landfills structures could be designed in a more cost-efficient way taking advantage of recycled or by-products. Additionally, the research results demonstrate that the environmental protection requirements of landfills should be updated to correspond to the capability to protect the environment instead of the current simplified requirements related to advective transport only.

Keywords: landfill, contaminant transport, geological barrier, environmental protection, Structural Risk Analysing method (SRA).

1. Introduction

The Landfill Directive defines explicit and unambiguous requirements for the structures that can be realized without a need for separate risk assessment. In the case of deviations, the risk assessment is obligatory. However, the directive does not define unambiguous requirements or procedures for it. Based on the literature, the risk factors affecting the landfill bottom structure can be divided into factors related to the landfill operational environment and to the waste content (Guyonnet et al. 2009; Cossu et al. 2003; Katsumi et al. 2001; Giroud et al. 2000; Korkka-Niemi & Salonen 1996; Christensen et al. 1994; Othman et al. 1994; Shackelford & Daniel 1991). Figure 1 presents the division of the most common identifiable factors related to the landfill operational environment and waste content, which affect the environmental protection crucially.

Based on the inadequate results of landfill risk assessment, it can be stated necessary to introduce further developed landfill risk assessment methods (Pollard et al. 2006). Risk assessing helps to define the risk factors, which have been identified in the designing phase and how their impact has been taken into account. The Structural Risk Assessment (SRA) method is introduced in this paper and is a tool for a sustainable landfill designing process. The SRA method gives substantially more information for landfill management, risk management and risk identification compared to the risk assessments conducted in the environmental permit processes.

The SRA method has been verified in the environmental permit processes of two landfills. The first verified case was an innovative surface structure and the second one a hazardous waste bottom structure. These verified structures used local products, by-products or recycled materials as much as possible to supplant natural materials and offer a substitute to expensive materials, such as sand bentonite. Also, these materials have to fulfil environmental regulations; otherwise authorities may not issue an environmental permit.

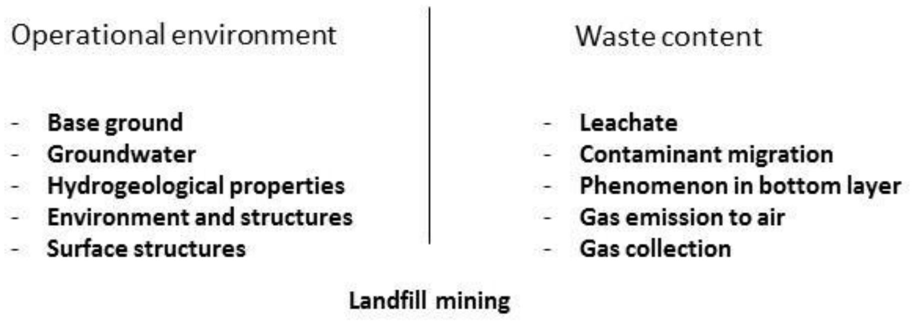

Figure 1. Effects of the most common identifiable factors related to the landfill operational environment and waste content on the landfill life-cycle information management and environmental protection (Ortner et al., 2014; Laner et al., 2012).

2. Materials and methods

2.1 Landfill surface structure

The risk assessment process was to find a solution for a lightweight structure that fulfils the environmental protection demands and is cost-effective. The incinerator has been activated recently and the surface structure should be possible to open for landfill mining purposes. The life expectancy exceeded 50 years because of the incinerator, landfill mining and the separation of waste (Pivato & Morris 2005). Landfill gases generate undesired odours in the vicinity of the landfill, and this could be avoided after the surface structures have been installed. Near the landfill site is a moraine area that has been tested during the landfill site construction, and the material could be used in the sealing structures. According to measurements by the Finnish Meteorological institute, the average drainage capacity is 548 mm/year. The temperature is below 0 degrees Celsius for 158 days a year.

The study was initiated with laboratory tests, calculations of gas emissions and water migration through porous media in a partly saturated situation. The risk quantification for uncertain assessment calculations had to be at least 1.5. The exposure assessment demands were set to control the water migration and electrical conductivity measurement results outside the landfill site in real time. The significance of electrical conductivity measurements is to control and secure that surface structures do not affect the surrounding environment. Electrical conductivity was chosen because the measurements easily indicate if harmful substances increase in the landfill areas, and comprehensive advance material is available as a reference (Grellier et al., 2006).

The hydrogeological properties, drying and shrinkage factors, insulation properties, frost resistance and mechanical properties of till were tested in laboratory conditions. The calculations of mineral layer hydraulic properties were simulated according to the Van Genuchten equation for partially saturated soils, the drainage system capacity according to unit gradient method and the bearing capacity with the general shear failure method. A drainage core was included in the gas collection layer. Table 1 illustrates the laboratory tests.

Table 1. Till's laboratory tests results.

Property, [unit]	test 1	test 2	test 3
Hydraulic conductivity [m/s]	2.2 E-8	1.7 E-8	6.6E-9
Effective stress [kPa]	26	40	20
Water content [w %]	5.2*	5.0*	9.5*
Dry unit weight [kN/m^3]	20.11	20.49	21.26
Volume shrinkage [%]	0	0	0
Compression strength [kPa]	73	75	72
Shearing strength [kPa]	36.5	34	37.2

2.2 The bottom structure of a hazardous landfill

The risk assessment process was to find a solution for a sustainable structure that fulfils the environmental protection demands and the life-cycle expectancy exceeded 50 years. The structural dimensioning was partly based on meteorological background information. Also, the result of the absorption tests was essential.

The average drainage capacity, founded on the precipitation statistics of the Finnish Meteorological Institute, is 513 mm/year. By 2012, the maximum precipitation during the preceding 40 years was 900.5 mm/year. The air temperature was below 0 degrees Celsius for 108 days and the soil temperature 217 days.

The background research included laboratory tests, a site investigation by boring drill holes into the solid base rock, taking samples from the drill holes, and absorption tests of water sludge made from existing landfill leachate. The objective of the absorption experiments was to examine the absorption capacity of water sludge and leachate, the impact of leachate on electrical conductivity, pH, and the chromium, molybdenum and nickel liquid-solid content. The risk quantification for uncertain assessment calculation had to be a minimum of 1.5 or at the same level as the frame of reference values. The exposure assessment demands were to control the electrical conductivity measurement results outside the landfill site in real time.

One of the primary principles was to make sure that the HDPE membrane does not include any holes after installation. There are several methods to confirm the integrity of the membrane. In this case, the electrical tension difference method has been used. The integrity of the membrane was crucial for structural dimensioning.

2.3 The Structural Risk Assessment method

The SRA method is useful to all landfill stakeholders: owners, designers, authorities and residents in the vicinity of the landfill. However, its most essential task involves design. The SRA method a tool for landfills risk assessment, which can be divided into three main categories (Fig. 2):

* Human factors

* Environmental factors

* Technical factors.

In the first phase, the identification of the current operational environment begins by evaluating source information, i.e. by comparing monitoring information, which can be called reference data, and test results. The second phase concentrates on the impact of various mechanisms, local conditions and phenomena in the design phase in relation to the required environmental protection level. In addition, during the design process, the initial conditions in the current operational environment and their impact on the environmental protection requirements will be taken into account. In the third phase, the achieved total result of the design phase will be compared to the minimum environmental protection requirements that are based on laws and decrees. In the last phase, the planned landfill life-cycle length will be examined in relation to the monitoring system with the help of which the changes or damages in the structures can be predicted, along with their environmental impacts. Also the risk quantification safety factors and the ranking between the risk assessment factors have to be defined.

Each category item has been further divided into sub-categories. The risk quantification can be identified more easily in the design phase with the help of the classification. In the risk analysis, the selected factors are examined based on the hypothesis that unidentified risk management does not exist but only identified risks could be accepted. The method emphasises the observation of every single factor, but examines analytically whether the factor is identified as a risk or not. Based on the reference data, it can be analysed whether the important factors have been identified in the design phase. Also, the identified factors impact the life-cycle information from the management perspective. In addition, the classification would have indicated how much and what type of essential additional information would have to be produced with the help of the evaluation procedure.

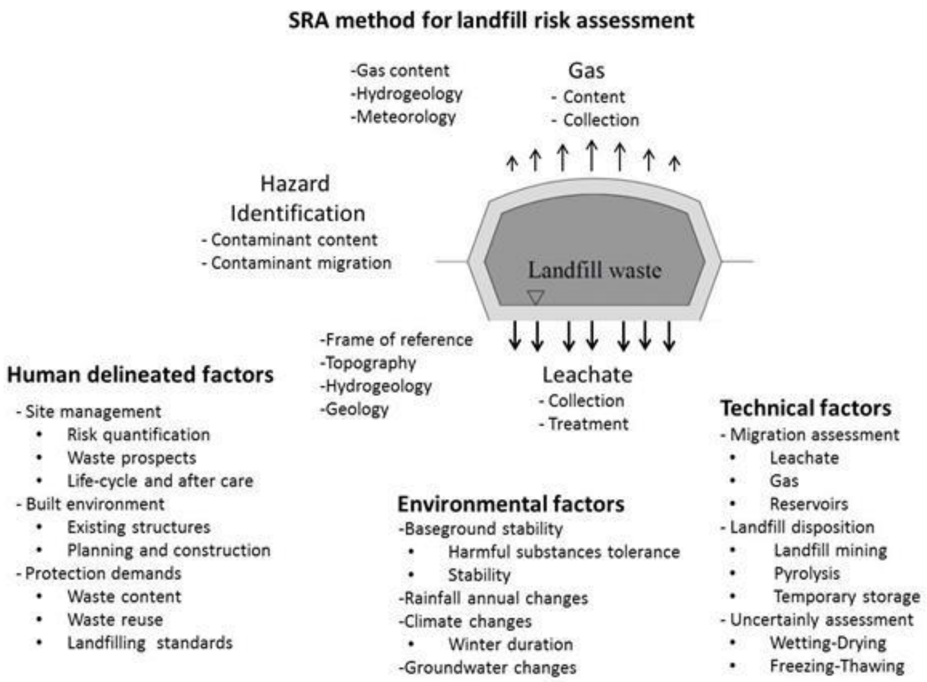

Figure 2. Risk assessment according to the SRA method.

The SRA method begins with the identification of the source data out of each entity of affecting factors, based on which it can be confirmed in the designing phase that there is enough source data available for decision-making in the design process. The minimum amount of source data depends on the target: is the landfill new or old, will the risk assessment being full or partial?

Typically, the source data would be more reliable if statistics could be calculated or the frequency of the data could be evaluated.

Unidentified risk factors will not necessarily cause risks during the whole landfill life-cycle, but the risk assessment is challenging if a risk has not been identified and its impacts have not been acknowledged in the design phase. The method does not guarantee risk-free environmental protection at the chosen risk level, because it is mainly a tool for the design phase. Errors during the construction phase may result in deviations in the selected life-cycle information management risk level and cause problems to the environment. For this reason, monitoring information should be utilised in the life-cycle information management after the design and construction phases.

Risk factors have to be ranked (P_x) after identifying them from the source data. P_x is the ranking value of an identified risk factor. Also, the landfill management or the designer has to determine the acceptable total risk level (R_{total}). The total risk level includes identified risk factors (R_{id}) and unidentified risk factors R_{ud}. The risk factor ranking depends on the structure protection demands, regulations, protection environment and human factors. This will lead to the situation that every risk assessment process has to be determined case by case. In addition, all the dominant risk factors are not included in regulations and environmental permits. Landfill management must identify the risk level (R_{ud}) of these unidentified risk factors.

The total risk level calculation is shown in Equation 1:

$$R_{total} = \sum_{x=1}^{n} R_{id} + \sum_{x=1}^{n} R_{ud} \qquad (1)$$

The identified risk level (R_{id}) can be determined by using Equation 2:

$$R_{id} = \sum_{x=1}^{n} P_x * Q_x \qquad (2)$$

Q_x is the probability coefficient of the identified risk.

The unidentified risk level (R_{ud}) can be determined by using Equation 3:

$$R_{ud} = \sum_{x=1}^{n} P_x * \beta_x \qquad (3)$$

β_x is the probability coefficient of the unidentified risk.

The probability coefficient Q_x of identified risk factors is always higher than demanded in regulations or environmental permits. The probability coefficient of unidentified risk factors could vary because increasing the reliability of the other risk factors could compensate for it. For example, the drainage layer risk probability is due to the fact that the soil is not being able to protect environment by increasing contaminant migration. Furthermore, the total risk level has to fulfil the demanded risk level. Figure 3 presents an example of a landfill risk assessment with the SRA method.

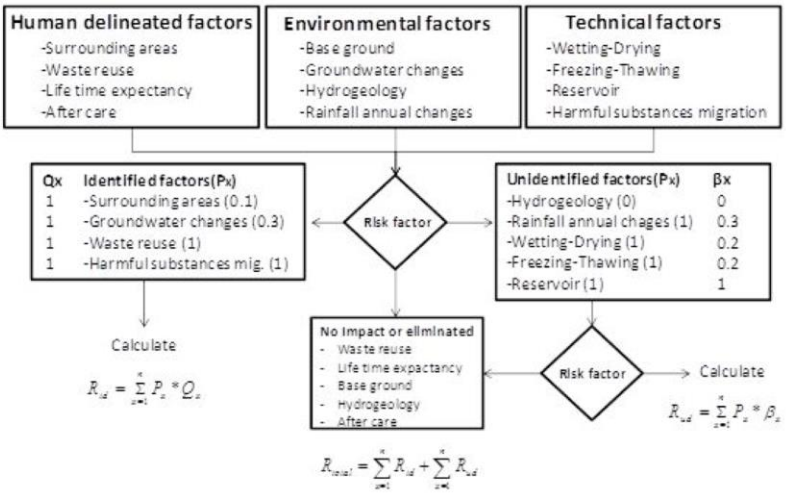

Figure 3. An example of landfill risk assessment with the SRA method.

3. Result and discussion

3.1 Landfill surface structure risk assessment with the SRA method

According to calculations, the surface structure environmental protection capacity of a mineral layer with a thickness of 0.09 meters could meet Government recommendation if fully saturated. Laboratory tests substantiate that the mineral layer could not reach full saturation in any meteorology condition (Henken-Mellies & Schweizer 2011). Consequently, partial saturation is a relevant calculation principal. Tammirinne et al. (2004) have made a model for surface structure drainage, but this model assumes that the temperature above 0 degrees Celsius throughout the year. The assumption is meteorologically irrelevant, but the model has been modified to be more realistic and relate to weather conditions in the landfill area. Tables 2 and 3 include mineral layer calculation results of dimensioning and safety factors. The dimensioning is calculated including and excluding safety factors.

Table 2. Dimensioning and risk factor calculation results for a surface structure mineral layer.

Property,[unit]	Including safety factor	Excluding safety factor	Risk factor
Hydraulic conductivity[m/s], (partly saturated conductivity)	$4.6\ 10^{-11}$	$1.3 \cdot 10^{-11}$	3.5
Effective stress [kPa]	26	13.7	1.9
Saturation degree [%]	40	30…50	---
Mineral layer thickness [m]	0.2	0.09	2.2

Table 3. Dimensioning, risk factors and total risk factor for the structural dimensioning of the surface structure drainage layer.

Property,[unit]	Including risk factor	Excluding risk factor	Risk factor
Flow rate [l/m^2s]	$2.38\ 10^{-1}$	$7.26 \cdot 10^{-2}$	3.3
Effective stress [kPa]	20	13.3	1.5
Gradient [-]	0.25	0.14	1.8
Structural dimensioning and total risk factor	2.05	1.5	**2.4***

*Note: * Total risk factor of the SRA method.*

The layer thickness has been increased form 0.09 meters to 0.2 meters because of construction and dimensioning problems. A very thin-layer construction over the angle slope would be challenging to excavate. Under Finnish regulations, the maxi-mum fraction size of soil material, such as till, has to be at least five times smaller than the constructed structure thickness. The maximum fraction size of till is 32 mm. Based on these factors, the 32 mm fraction size is a good reason for the thickness of the layer. According to frost resistant tests, water sources could not determine the freezing-thawing phenomenon for the mineral layer structure. The calculated total risk factor value was 2.4. The total risk factor value is the sum of the identified risk factors, and the ranking of the risk factors of this structure is the same (1).

The cost-efficiency of the structure compared with Government recommendations is 14% more affordability per hectare. The cost-efficiency will increase if the structure is opened in the future, because the structures are thinner and easier to excavate.

The limit conditions stated in the EC Landfill Directive should be developed further by means of structure life expectancy calculations, which can be implemented using various methods, such as the conversion factor method, statistical measuring and limit state of fatigue measurements, and the risk assessment safety factor.

3.2 Risk assessment of the bottom structure of a hazardous landfill with the SRA method

The structural dimensions of the geological barrier, water sludge, are shown in Table 4. The barrier is 1.2 meters thick, and the calculated risk level is 1.78. Hydraulic conductivity determined by 100 kPa effective stress, which is 1/6 of the final situation when the landfilling is finished. The porosity could be much lower in the last few years of landfilling because the effective stress increases and causes loading. The hydraulic conductivity will decrease impact on porosity and also affect the transport equation.

Table 4. Geological barrier's structural dimensions, calculation coefficients, porosity and contaminant transport times for three layer thicknesses.

C/C_0 =0.1 [Years]	Layer thickness [m]	Hydraulic conductivity [m/s] *	Hydraulic gradient [-]	Diffusion coefficient [m^2/s] **	R [-]	Porosity (-)
63	1.0	$4.5 \cdot 10^{-10}$	1.5	$2.0 \cdot 10^{-10}$	1	0.4
89	1.2	$4.5 \cdot 10^{-10}$	1.42	$2.0 \cdot 10^{-10}$	1	0.4
118	1.4	$4.5 \cdot 10^{-10}$	1.33	$2.0 \cdot 10^{-10}$	1	0.4

*Note: * The hydraulic conductivity value was determined by 100 kPa effective stress that is 1/6 of the final situation when the landfilling is finished. ** The diffusion coefficient is based on calculations by Katsumi et al. (2001).*

The HDPE geomembrane will be installed above and under the water sludge layer, also called the geological barrier. A double layer geomembrane could secure the migration of harmful substances of water sludge to the soil. The drainage layer and the leachate will be collected separately when the HDPE geomembrane is installed. This enables the control of the leachate source and content in both layers. Leachate is conducted to the reservoir and further to water treatment.

The uncertainty of the risk assessment has been estimated by determining the content of the drilled ground samples. The sample test results have been compared with the Government decree limit values and natural values (VNa 214/2007). Table 5 shows the reference values for soil.

The total risk value is the sum of the identified and unidentified risk factors and the ranking of the risk factors of this structure is the same (1). The total risk factor (R_{total}) was 1.79. The cost-efficiency of the structure compared with the Government decision is 43% more affordable per hectare. The total cost-efficiency is influenced most by the possibility to use by-products as a part of the structure.

Table 5. The examples test results compared with Government decree limit values and natural values.

Substance	Unit	Frame of reference	Limit value	Natural content	Lower reference value	Upper reference value
Chromium (Cr)	mg/kg	30*(25-48)	100	31(6-170)	200	300
Molybdenum Mo)	mg/kg	<1*	-	<1	<1	<1
Nickel (Ni)	mg/kg	10*(8-13)	50	17(3-100)	100	150
pH	-	7*(6.2-7.8)	-	-	-	-

Note: * Outside of the bracket is the mean value of 12 measurements and inside of the bracket are the lowest and the highest determined values.

Typically in environmental protection structures, attention is paid mainly to the hydraulic conductivity of the mineral layer. The landfill structure analysis should take into account the leachate management, and in leakage situations the leachate content, human-related factors and waste prospects in the risk assessment. Essential factors for the securing of the landfill barrier structures' operation are the functionality of the drainage layer and the intactness and life-expectancy of the artificial barrier. If it is possible to conduct the leachate from the bottom structure through the drainage layer into treatment during the whole life-cycle, the hydraulic gradient to the bottom structure is not significant. This reduces the leachate stress on the mineral layer including all transport mechanisms. From this example, the effect of the hydraulic gradient is eliminated because the artificial layer will be controlled to avoid damage after installation. Therefore, during the active phase the artificial and drainage structure will eliminate the effect of the hydraulic gradient.

Factors related to material transport and retention and contaminant migration have been discussed above. Based on them, it can be concluded that an unambiguous correspondence between the materials and structures is not easy to determine. The definition of reference materials or structures is also difficult because some materials may be better than others in some respect. Instead, materials and structures can be compared in relation to functional requirements. Dominant factors may in some applications be the amount of penetrating water and in some applications the penetrating contaminants or their concentrations or the time needed for their accomplishment. In structural analysis, the identification of the dominant factors and the setting of boundary conditions are essential and significant. According to the results of this thesis, the boundary condition setting has to be based on landfill-specific requirements, which may vary significantly depending on e.g. the location of the landfill, hydrogeology, meteorology and topography.

The SRA method is the most suitable for materials like these, that is, industrially by-produced materials for which the manufacturer can provide a serviceable life estimate for comparison. Statistical measurements support the SRA method for measuring structure dimensions, since the measuring equations are presented as a fatigue parameter and a response parameter so that the parameters are time-dependent. One example of this is the contaminant migration equation in which a concentration differential forms as a function of time due to the effects of fatigue caused by different loads.

4. Conclusion

The overall aim of this research was to provide further information on how the landfill risk assessment process has to be focused according to human-related, environmental and technical factors while evaluating the possible risk assessment to the environment. The technical requirements of the present landfill protection structures cannot achieve sustainable protection by focusing on the landfill life-cycle risk assessment information. The most essential problems in the design period are the unidentified and unrecognised risk factors and their effects on the landfill's environmental protection capability. The most significant factors are the inadequacies in the contaminant transport modelling and in the identification of the factors affecting it. Another essential factor is the identification of the factors affecting the environmental protection structures' capability and their life-cycle. In addition, the impacts of the existing structures or infrastructure on landfills have not been identified.

The directive should be developed to include complete guiding principles for the risk assessment scenario. The inconsistency in risk assessment leads to overly optimistic solutions and does not observe crucial requirements such as the local climate and weather. Unfortunately, it seems that numeric goals are missing in the directive. The directive only defines hydraulic conductivity and layer thickness, enabling different interpretations.

The results of this study emphasise the importance of utilising risk assessment like the SRA method for designing landfill structures. The design parameters should be based on true technical and environmental factors, human influence, waste prospects and risk quantifications for the final result to acknowledge the existing hydro-geological environment. In the future, demands concerning landfills will change because of reuse, recycling and using landfills as a material source. In consequence, landfills will be used as temporary storage in the future. Therefore, tools such as the SRA method will be needed to evaluate the life-cycle of landfill structures from different angles.

Minimizing Risk through Performance Rather Than Warranties

Dean Kashiwagi, Dhaval Gajjar and Luisa Santana Carvalho

Abstract

Many problems are caused by owners specifying project technical requirements to expert vendors, then picking the low price vendor, assuming that all the vendors are providing the same quality of product. Research in the last 20 years has identified that when working with highly technical areas, this practice brings high risk to the owner because the vendors do not have the expertise to understand the requirements. The Alpha sprayed polyurethane (SPF) roof system has brought the Dallas Independent School District (DISD) high value but also occasional risk caused by the low price vendor. The authors are proposing that DISD's effort to buy the Alpha SPF roof system through the low price competition will cause DISD risk. A new approach is proposed to DISD, that the Alpha SPF roof system only be used as an alternate value added option. This approach assumes that the only way the Alpha SPF system can be procured is if it is in the best interest of the owner due to dominant value. This approach minimizes the risk that DISD has encountered from low price contractors who have not been able to minimize risk through the use of expertise and experience because their low price was directly related to a lack of experience and expertise.

Keywords: roofing, Alpha Program, Sprayed polyurethane, Best Value, performance

1. Introduction

Sprayed polyurethane foam (SPF) roof systems have been installed since the early 1970s. SPF roof systems have the following characteristics:

1. Have the highest insulating factor of any roof insulation systems.
2. Have the lowest weight of any roofing system [0.50 PSF (3 PCF)].
3. Monolithic.
4. Has a very technical application utilizing an exothermic reaction that transforms two liquid components into a rigid three pound density SPF.
5. The industry has changed the insulating refrigerant material numerous times to meet EPA standards, causing applicators to change their temperatures and process details.
6. It is a sustainable and green roof system [renewable, minimizes the need to remove the existing roofing system and lightweight].

7. The SPF industry has had difficulty regulating itself, resulting in many SPF roof failures.
8. Properly installed SPF roof systems have performed very well. The industry has always remained less than 3% of the roofing industry due to their inability to regulate the performance of their contractors.
9. SPF roof systems require a coating system to protect it from UV degradation.
10. Confusion on the performance of different coating and SPF roof systems [hail resistance, UV degradation and ability to sustain roof traffic].
11. Warranties are used by sales/marketing personnel to attempt to identify performance.
12. Warranties are used as marketing and are not related to performance.
13. In 2001, when coated SPF systems failed at DISD, and the manufacturers did not honor the warranty, DISD stopped using coated SPF roof systems.

An example of illogical warranty and marketing information was provided by Factory Mutual, [one of the two largest building insurance groups], who put out a report that all coated SPF systems, offer hail protection against 1-3/4 inch size hail based on their hail testing. PBSRG testing in 1996 could not verify their results. There published results identified silicone coating as the most hail resistant, and urethane coatings as offering the worst protection. PBSRG tests found it was the exact opposite [Kashiwagi & Pandey 1996]. FM testing was done only on new coatings and coating systems that were weathered using artificial weathering. When actual aged systems in the field were tested, the results verified that the Alpha urethane coating was the only coated SPF roof system that offered protection against 1-3/4 inch size hail. [Kashiwagi & Savicky 2003]

Only one SPF coating system has documented high performance in heavy hail areas. The Alpha system, made by Neogard, is the only coated SPF system with documented protection against hail. Other urethane coatings have not documented the same protection after being exposed to the elements.

DISD used the design-bid-build procurement approach to award contractors to install SPF roof systems. The resulting poor performance of SPF roof systems led to a DISD policy of “no SPF” roof systems on DISD roofs. It has not been proven that the price based approach can be used to utilize the value of the hail resistant Alpha SPF roof system.

2. Dallas Independent School District

From 1987-2001, DISD had a few high performance Alpha SPF roof systems, but the majority of the SPF systems failed. It was common for the coating and SPF manufacturers to offer warranties but not honor those warranties. Since DISD could not utilize their warranties and due to poor performing SPF roof systems, in 2002, DISD banned the installation of SPF roof systems.

DISD is in a heavy hail area, and is self-insured against hail damage. DISD identified that the Alpha roof system [with sufficient urethane coating] on the Casa View School roof showed 16 year performance with no maintenance. In 2002 DISD allowed the installation of the Alpha SPF roof system in a best value procurement test to identify if the same high performance could be duplicated. The results showed that the Alpha SPF roof systems were installed with high performance [Kashiwagi & Savicky 2003]. Due to the dominant performance results, DISD changed their policy and allowed the installation of the Alpha SPF roof systems.

In addition to the test results, the Neogard Corporation supported the Alpha roof system with a joint and several warranty, covering the performance of the SPF and the Alpha coating system. These warranties held the insured parties [Alpha coating manufacturer, SPF manufacturer, and the Alpha contractor] joint and severally, liable for any defects of the system. Defects included blistering and delamination. Defects that were not covered by the SPF industry were covered by the warranty [leaking was the only recognizable defect covered by warranties]. The joint and several warranty, along with the proven performance of the Alpha roof system in hail areas, differentiated the Alpha SPF roof system and help convince the DISD to continue to install the Alpha roof system.

In 2005 DISD had bond program to renovate their school buildings. The bond program eventually ran short of funding. Due to the shortage of funding, DISD did not utilize the Alpha SPF roof system and its warranty, but utilized a ten year SPF system, with a more traditional 10 year warranty. The ten year urethane coated SPF system [no joint and several warranty] was still at a much lower cost compared to the traditional built up and modified roof systems. The contractors bids were shopped, and one of the contractors used a SPF system that was not utilized in the Alpha program.

Table 1 shows the SPF roof performance of the Alpha roof systems at DISD based on the physical inspections of 98 roofs. Evaluating roof coverings using physical inspection and reporting the repair or replacement conditions to the owner have been used for other roofing systems [Coffelt et. al. 2010, Sharara et. al. 2009]. Table 2 compares the blisters and repairs at DISD for the last 4 years.

Table 1 – Overall DISD SPF Roof Performance

Despite the low bidding and shopping of the Alpha roof contractors bids, DISD has received performance from the roofs that were installed. One of the reasons for using the Alpha roof system was the Alpha program required their contractors to maintain 98% customer satisfaction and roofs not leaking on an annual basis to continue to be allowed to install the Alpha roof system. This included all roofs that were installed by the roofing contractor. If they had issues that resulted in customer dissatisfaction, they were required to fix the roof. This resulted in many of the DISD roofs being maintained by the contractors, not as a warranty requirement, but as a requirement to get further work at DISD.

However, the following factors led to a degradation of the some of the contractor's roof system performance:

1. The Alpha roofing contractors are shopped for price through general contractors and traditional roofing contractors.
2. A relatively new contractor, who needed work, took the majority of the work due to their very low prices.
3. The low price contractor used substandard SPF due to a shortage of SPF material.
4. The low price contractor had an excessive amount of work and ended up cutting corners, such as installing SPF in marginal conditions.

In studying the defects of the Alpha system, it is clear that the majority of the problems were contractor generated. Requiring the manufacturers to pay for the repair of the defects under a ten year warranty, cannot be enforced. Once the contractor is paid, there has not been a way to force the contractor to fix the defects. If the defects are large, the contractor will go out of business. If the roofing system did not have a joint and several warranty, the roof owner has no recourse but to install another roof.

The low price contractor installed 62 out of the 98 roofs and there were 16 roofs which had defects that required maintenance. The contractor did not charge enough to maintain their roofs through the ten year warranty period [DISD expectation]. The roofing manufacturers [alpha coating and SPF manufacturer] continued to sell their materials to the contractor. DISD continued to hire and utilize the contractor. The contractor began to have issues with their roofs, and was not doing their maintenance work to keep the roofs performing. They ended up going bankrupt in

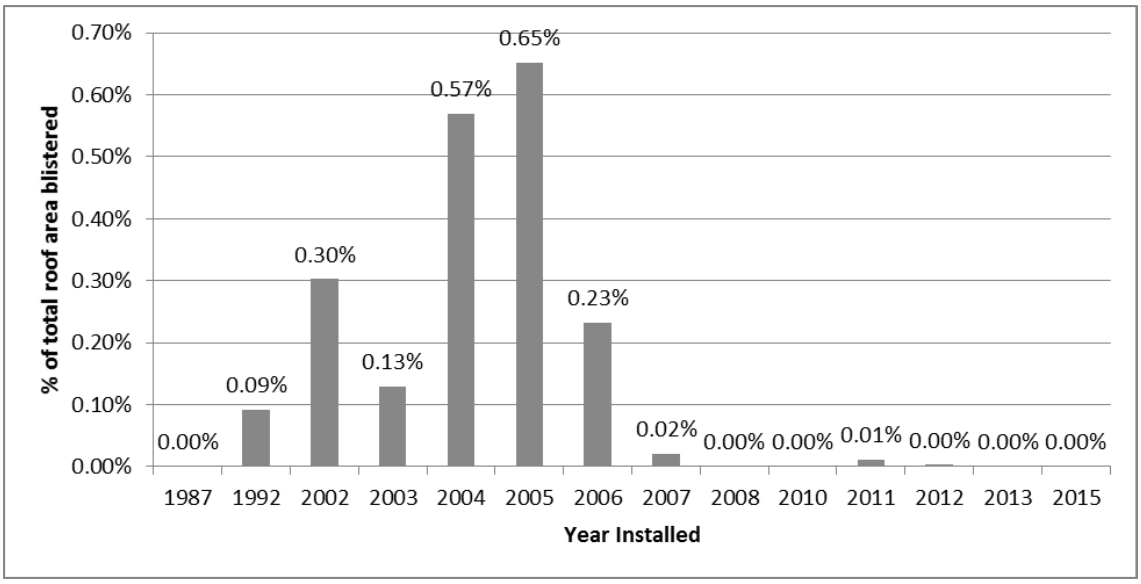
2015. DISD requested Neogard to cover the warranties, but with the ten year warranty, Neogard and their SPF manufacturing partner BASF, did not cover the SPF roof defects.

Table 3:# of Roofs Installed Yearly

Year	*# of roofs installed*	*Year*	*# of roofs installed*
1987	*1*	*2007*	*1*
1992	*1*	*2008*	*5*
2002	*3*	*2010*	*12*
2003	*1*	*2011*	*9*
2004	*15*	*2012*	*6*
2005	*28*	*2013*	*1*
2006	*11*	*2015*	
2007	*4*		

Another analysis of the roofs show that the majority of the problem roofs were installed in 2014 and 2015 during the beginning of the 2004/2005 bond program (Table 3). Ten years later the roofs show the problems which could have been avoided with more careful installation, and better materials. Despite a number of poor performing roofs, the number of performing roofs outnumber the poor performing roofs (Table 4). To identify the performance of a few nonperforming roofs due to extenuating circumstances in the bond program, with the performance capability shown on other roofs that are installed correctly would minimize the value that the DISD could receive from the Alpha SPF roof system.

Table 4: Roof Yearly Analysis



3. Problem

The warranties accompanying the coated SPF roof systems could not be enforced. The warranty is provided by the manufacturer to the buyer as a protection [Agrawal et. al. 1996]. Since the manufacturer provides the warranty it is written by their legal representatives [Murthy & Djamaludin, 2002] and contains exclusion that will void the warranty if encountered [Christozov et. al. 2009]. Hence warranties have no proven correlation to the actual performance of the product, however, contractors still use them for marketing purposes [Kashiwagi 2012]. Similar to the history of the SPF roof industry, where warranties were used as marketing tools to convince building owners that a longer warranty meant that they had a longer performing roof system with protection against defects, DISD found themselves with a few SPF roofs with problems which were not protected by the warranty.

DISD is aware of the value of the SPF roof systems when they are installed correctly. They are also aware of the impact of the "low bid" delivery system on the value and performance of the roof system. There were additional problems that DISD and the Alpha coating manufacturer (Neogard) encountered:

1. Neogard did not get the needed support from the SPF manufacturer that they had partnered with. The SPF manufacturer charged a higher price for the Alpha SPF, but offered no added support for the needed maintenance repairs.
2. Neogard no longer wanted to cover the liability for the correct installation of the SPF.
3. The contractors did not have the sufficient business acumen to take needed steps to minimize the risk of SPF roof defects.
4. The bonding companies were charging unaffordable rates to cover joint and several warranties. Due to this the contractors were not willing to sign the joint and several warranty.
5. DISD had 4M Sf of the Alpha system installed and had seen it was a good value proposition. However, DISD wanted a joint and several warranty, and none of the vendor parties were interested in taking on the liability.

The challenge to the Alpha coating manufacturer and DISD is:

1. To create a system that self-motivates the contractors to install a quality roof system.
2. Motivate the SPF manufacturer to take accountability of the SPF performance.
3. Minimize the risk of a non-performance at key points in the installation process, therefore minimizing and not transferring risk of non-performance to non-responsible parties.

Table 5: Roofs with High Damage (Over 1% Blistered)

School	*Roof Area in SF*	*Date Installed*	*Contractor*	*Total SF of Blisters*	*% of Total Roof Area Blistered*	*# of Blisters over 1 SF*	*# of open blisters*
Russell ES	*27,295*	*May-04*	*Alpha Contracting*	*1,050*	*3.85%*	*10*	*5*
Samuel HS	*147,500*	*Aug-05*	*Alpha Contracting*	*4,000*	*2.71%*	*27*	*0*
Spruce HS	*85,000*	*Aug-05*	*Alpha Contracting*	*2,150*	*2.53%*	*25*	*7*

Lincoln HS - Flat	*12,000*	*Oct-06*	*Alpha Contracting*	*230*	*1.92%*	*4*	*1*
Hawthorne ES	*45,200*	*Jul-05*	*Alpha Contracting*	*660*	*1.46%*	*6*	*3*
Russell ES - Old Admin Bldg.	*10,500*	*Aug-04*	*Alpha Contracting*	*150*	*1.43%*	*0*	*0*
Terry ES	*28,400*	*Dec-04*	*Alpha Contracting*	*320*	*1.13%*	*4*	*3*
Peabody ES	*32,600*	*Aug-05*	*Alpha Contracting*	*350*	*1.07%*	*7*	*4*

*All the high damaged roofs were installed in 2004, 2005 and 2006 and account for 66% of all blisters at DISD.

4. Approach and solution to the Problem

The steps to the solution of this opportunity must include the following:
1. Identify the DISD delivery system of construction and construction systems.
2. Identify the value of the Alpha roof system.
3. Identification of the source of risk caused by non-performance and create a new system that minimizes risk due to the structure of the approach and does not depend on a warranty to minimize non-performance [has not worked at DISD in the past ten years].
4. Create a best value structure that minimizes the risk of non-performance.
5. Create a transparent environment that clearly identifies expertise and the source of risk.

5. Description of the DISD Procurement/Delivery System

The DISD delivery system of construction is a design-bid-build (DBB) delivery system. The designers in the system do not have accurate information of the performance of different roofing systems and therefore do not have the expertise to select or design highly technical roof systems. They also do not have the legal liability or accountability of the roof system performance over the duration of the roofing system's lifespan. Due to the lack of information, the designer's decision making increases risk. The only party that does have the responsibility of roof system performance is the DISD roofing maintenance expert. He has the responsibility to resolve all roofing issues. Any change in roof system policy requires the DISD roofing expert's support.

The SPF roofing contractors and manufacturers in the DISD environment have shown the following characteristics:
1. There are vendors who cannot accurately price roof systems to accept the accountability of the performance of the roof for the duration of ten or more years. The Alpha SPF roof system should never be competed based on price.
2. Manufacturers of both the Alpha coating system and the SPF have not consistently exhibited leadership or control over the vendors pricing, installation and maintenance activities. Neither

have they consistently understood or supported the vendors at key times in the beginning of a project and at the end of the project to ensure the minimization of risk.
3. The Alpha SPF roof system has not consistently and successfully been competed among the SPF contractors. Rather than assume the cause of this lack of success, the Alpha SPF roof system should only be an alternate to the traditional modified or built up roof system, and should only be installed when the value to DISD shows tremendous value [cost savings of 30% or higher].
4. Warranties have shown minimal value in protecting the client against SPF defects and should not be used to protect the building owner. The more DISD depends on the warranties, the greater is DISD's risk.

6. Value of the Alpha SPF Roof System to the DISD

The DISD is in a heavy hail geographical area and is a self-ensured organization/entity. The Alpha SPF roof system has the following characteristics:
1. When installed correctly, proven 20 year history of performance in hail areas with the ability to withstand 1-3/4 inch size hail, it has been documented to resist larger hail, but due to the uniqueness of the hail shape and hail storm characteristics, expectations of hail resistance for larger hailstones must be tempered.
2. DISD documentation showing that the Alpha SPF roof system at DISD has exceeded 25 years [Foster Elementary and Casa View] and has the capability to be recoated for an additional 15 years [total of 40 years]. The aged Alpha SPF system's ability to withstand hail damage shows no degradation over time.
3. The Alpha SPF system does not require the removal of the existing Built-up Roof (BUR). Together with the BUR it forms a better waterproofing system. It does not require the throwing away of the existing roofing system which is environmentally friendly [Knowles 2005].
4. The Alpha SPF system is renewable through recoating.
5. The SPF is the highest known insulating material, and is monolithic which increases the insulation value.
6. The documented and observable value of the Alpha SPF system is 40 – 50% less that the price of the traditional BUR of modified roof system. This is established from the DISD base price of $16/SF for BUR vs the SPF pricing of Wattle & Daub [Tisthammer, identified as the best SPF performing vendor in the United States, 2015].

7. Risk of Defects in the Alpha SPF Roof System

Due to inconsistency in performance of the same roofing system, it has been observed that the craftspeople installing the SPF roof system, commit easily avoidable errors that lead to SPF defects. The industry expert [has been doing research for the longest duration, has help create the Alpha program for SPF roof systems, and has the most dominant performance in the SPF industry in the U.S.] stated that "the SPF system may exceed the planning and technical capabilities of the average SPF roofing manpower force." [Tisthammer, 2015] The defects observed over the past twenty years in the SPF industry are attributed mainly to applicator error [Bailey & Bradford 2005]. The number of occurrences that are due to material problems have been rare. The sensitivity of the chemistry of the SPF system when installed [temperature, ratio of the two components, not stepping on the cured system before it is cured, sensitivity to moisture, and not installing on a substrate with moisture], increases the need for expertise to follow specific installation instructions.

The defects require a system to assist installers to identify and mitigate risk that the installers may not instinctively do. This issue is not unique to the SPF industry, but is observable in the construction industry in general. Oftentimes, if the SPF installers have a discussion with the manufacturers' representatives, DISD roofing expert and other DISD involved stakeholders, many of the issues that cause risk can be eliminated. By observing the DISD Alpha SPF roof performance history, an on-site clarification meeting where the vendor's experts clearly articulate their concerns and challenges and then get input from the DISD and other stakeholders would have minimized most of the risks and defects encountered over the last 13 years at DISD.

The second observation of the DISD Alpha SPF roof history performance is that lab testing of the installed Alpha roof system must be performed, and the results analysed not only for the newly installed roof, but compared with the physical characteristics of all other installed SPF roofs at DISD. The results of the tests and analysis should be accessible to all stakeholders and to the industry. The current DISD environment has a lack of transparency of the technical metrics.

The third observation of the history of DISD Alpha SPF roof system performance is that any warranty documentation must be simple and the responsibility of the SPF and coating defects must be clearly stated. Once the Alpha coating and SPF physical metrics are checked and approved, the Alpha coating manufacturer is responsible for the coating defects, and the SPF manufacturer is responsible for the SPF defects. Another option is for the contractor to be responsible for all SPF defects. However, if the contractor is responsible, the risk is greater and the owner may require a performance bond due to the financial instability of roofing contractors.

8. Creation of a Best Value Structure for the Alpha Program

A best value structure is required for the DISD use of the Alpha SPF roof system. As previously identified, the Alpha program must have transparency, show responsibility and accountability and show expertise of the vendor to successfully install and maintain their Alpha SPF roof systems. This structure includes:

1. The inspection of a minimum of 50 performing SPF roof systems.
2. Have a 98% roofs not leaking and customer satisfaction of all SPF roof systems installed.
3. Annual surveys of all SPF roofs installed.
4. Every other year inspection of 25 or more roofs being installed.
5. Respond to a leak or customer dissatisfaction within a week, and fixing the defect with two weeks unless given more time by the owner's representative.

Any vendor who fails to meet any of these requirements at any time shall be suspended from the Alpha program. Re-entry into the program will require the above five steps to be redone.

9. Transparent Environment Built by the Manufacturers, Contractors and DISD

The best value environment is transparent. When an environment is transparent, the following characteristics are observable:
1. Consensus. All stakeholders will know the performance of any building system or vendor or system.
2. Metrics. All performance will be delivered in terms of relative number of years the roofs have been performing, initial and repair costs, number of leaks, was the leak fixed, the duration of time it took to be fixed and customer satisfaction.

The Alpha SPF roof system cannot be consistently and successfully specified and installed. The Alpha SPF system can only be selected and installed if the following is observed:
1. The budget for the traditional roof system is exceeded, and the Alpha SPF system can be installed within the constraints.
2. The Alpha SPF roof system is a dominant value [30% or more in cost savings of the specified system].
3. The alternative option which warrants all coating and SPF defects [with verifiable information that the manufacturer's system has been operational in covering defects]. The options that identify that the manufacturer will cover defects caused by their material has no value. It must state that the SPF manufacturer covers all SPF defects. This forces SPF manufacturers to cover the risk of applicators who do not respond to installation problems.

10. Conclusion

The Alpha SPF roof system has shown tremendous value for the Dallas Independent School District (DISD). However, the following are observations of the last 13 years of DISD attempting to deliver the Alpha SPF roof system using the low bid environment:
1. A few of the Alpha SPF roofing contractors have not been able to escape the low bid pressures that have led to occasional non-performance issues.
2. A high performance Alpha SPF roof system cannot be consistently delivered in the DISD low bid environment as lower performing contractors win jobs with low prices.
3. The Alpha coating and SPF manufacturers and DISD have not been able to regulate the contractor performance by proper quality control and the use of performance information.
4. There are Alpha SPF contractors who do not have the management and planning expertise and discipline to identify and minimize sources of SPF performance risk at the beginning of the project.
5. The Alpha SPF manufacturers have not provided the transparency that would have minimized DISD risk by testing for performance metrics at the end of the project, and continually comparing the project metrics to existing DISD Alpha SPF roof metrics.

Instead of using the traditional warranties which are difficult to enforce, the Alpha SPF manufacturers [Alpha coating and SPF] must create a new risk mitigation environment. The risk shall be minimized by identifying the sources of risk, and eliminating the sources of risk before the project begins instead of passing the risk to another party [traditional warranty system]. The DISD will also participate in the program by following simple rules of best value. The new environment will minimize risk sources regardless of who causes the risk.

The following are the risk mitigation mechanisms:
1. The SPF Alpha system should only act as an alternative to the traditional modified BUR system and can only be selected if it shows tremendous value for DISD [a minimum of 30% cost savings]. The Alpha roof system is already identified as an alternate roof system in the DISD approved specifications.
2. The SPF alternative proposal will be selected if the SPF manufacturer covers all SPF defects regardless of cause [and shows an operational process that has been in place] and still shows dominant value over the traditional specified system [minimum of 30% cost savings].
3. A clarification period will be held on every Alpha SPF project that is approved that requires the manufacturers' representatives and DISD stakeholders to attend. The Alpha contractor should clarify how they will install the Alpha system, present a list of risks and risk mitigation and have a schedule that will be tracked throughout the project.
4. The contractor will have third party inspection of the roof of coating thicknesses and SPF density, compressive strength and material stability. The testing metrics will be in a system that is accessible to all and easy to understand, creating transparency in the event that there are performance issues during the service period of the Alpha SPF roof system.
5. The contractors will show their level of expertise by belonging to an Alpha performance program that monitors the performance of all their SPF roof applications.
6. This Alpha program suspends the contractor if they do not follow any of the requirements of a high performance contractor [maintains their roof systems, maintains customer satisfaction and roofs not leaking to a 98% level of performance, and fixes any deficiencies within two weeks of notification].

Improving the Resilience of Roofs: Lessons from Wind Damage Reports

Keith Roberts
Roberts Consulting, Abingdon, UK
mail@robertsconsulting.co.uk

Abstract

As wind strengths increase in the future there will be requirements to assess the roof attachment strength of existing buildings. Improving the resilience of roofs to wind damage follows from an understanding of load transfer paths through the multi-layer roof systems.

Several case studies of wind damaged roof investigations in the UK and Ireland are presented, exploring alternative causation theories and identifying the weakest links in the roof attachment.

It is hoped that by sharing feedback from wind damage reports in an independent and constructive way we can improve our common understanding of failure mechanisms, enabling us to design and build more resilient building envelopes that are better able to withstand the extremes of changing weather patterns.

Keywords: roof resilience, roof reliability, wind damage

1. Introduction

Technical investigation reports on wind damage to roofing and cladding can provide a wealth of useful information relevant to designers, researchers, manufacturers, contractors and building owners. It is common to find multiple failures within roof systems and often the challenge is to identify which link in the assembly broke first. The forensic investigations demand a methodical approach, piecing together the available evidence of the initial point of failure, which is often hidden from view.

Several case studies of wind damaged roof investigations in the UK and Ireland are presented, exploring alternative causation theories and developing options for strengthening and repair.

This paper describes the method used for determining the attachment strength of a profiled metal roof construction under wind suction loading. Improving the resilience of an existing roof is dependent upon the identification of the weakest links and strengthening them.

2. Background

2.1 Extreme wind events

Situated on the edge of the North Atlantic Ocean, the islands of the United Kingdom experience storm force winds with gust speeds of 30 – 40 m/s occurring several times each season. Major storms can result in personal injuries and significant financial losses. In an average year 200,000 buildings are damaged by high winds, although the majority of insurance claims are for minor losses of ridge tiles on older properties. This was described by Blackmore (2003). The prevailing wind direction in the UK and Ireland is from the south west as frontal depressions track across the North Atlantic. Winds blowing from the north and east tend to be less severe and cause less building damage.

In recent years there have been several significant wind events where recorded wind speeds in isolated locations have been greater than could be expected to occur once in fifty years. If these events were to recur then our basic wind speed maps may need to be revised. However, at present no plans have been published to update the relevant standards.

It is understood that the increase in extreme wind events is related to changes in the paths of the jet stream, with broader meander patterns and increased velocities. Various explanations for these changes have been offered, although at present there does not appear to be a broad consensus. There is uncertainty in the longer term forecasting of weather patterns and predicting maximum wind speed data for future building design. What is predicted with a high degree of confidence is that more extreme weather events will occur.

2.2 Roof attachment strength

Wind suction forces acting on the outer weathering skin of a roof are transferred from layer to layer down through the roof construction into the structural framework. Each connection transfers the upward load to the next layer down. A useful analogy is that of a chain anchoring the upper weathering skin down to the support structure. If one link in the chain were to break, then potentially the outer sheets can become detached from the roof. As part of routine design calculations should be prepared to estimate the design wind suction loads acting on the different links in the chain and then compared with the characteristic strength of the fasteners to determine their factors of safety.

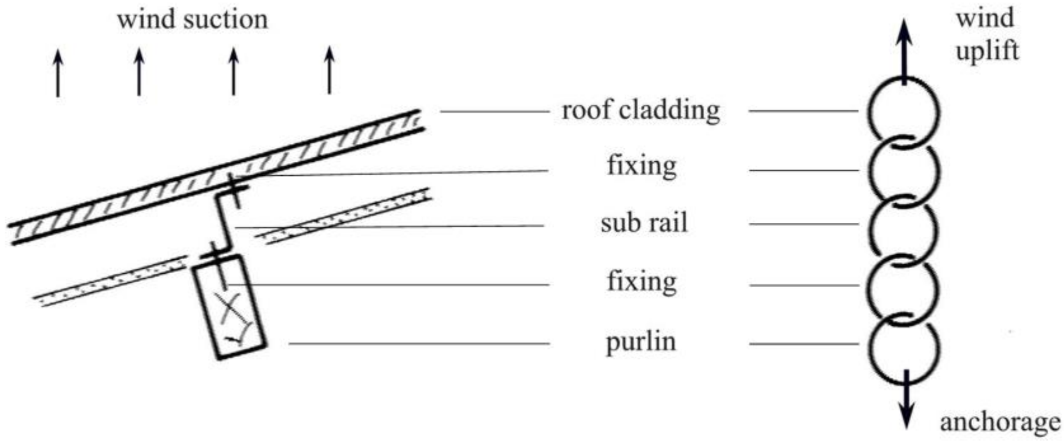

Figure 1: The chain analogy for the attachment strength of a multi-layer roof system

A protocol for the assessment of wind damaged roofs in North America is described by Smith (2013). Within the UK a permissible stress approach is still used for checking the attachment strength of a profiled metal roof, as described in BS 5427 (1996). The design wind pressures acting on the roof are calculated in accordance with BS EN 1991 Part 1.4 (2004). The permissible strength of the roof assembly needs to be greater than the applied pressure.

$$\mathbf{w} < \frac{\mathbf{f}}{\boldsymbol{\gamma}}$$

where: w = design wind load
f = characteristic strength
γ = factor of safety

The minimum factors of safety used in the UK for checking the attachment strength of profiled metal and single ply membrane roof fasteners, are 2.0 for pull-out from steel or aluminium, 3.0 for pull-out from timber and 4.0 for pull-out from masonry or concrete.

From the calculations for the roof assembly the greater the factor of safety, the greater the resilience of the roof.

3. Wind damage investigations

3.1 Case study A: standing seam roof

On New Year's Day 2005 a strong gale blew across southern Ireland resulting in an extensive area of lightweight aluminium standing seam roofing becoming detached from the windward verge and causing significant consequential impact damage to roof cladding and rooflights downwind. The aquatic centre and adjacent gym were evacuated safely without injury to members of the public or staff.

Location	Dublin, Ireland
Building use	Aquatic centre
Altitude, site exposure, topography	+74 m severe, rural
Roof area	5,700 m^2
Roof slope	Barrel vault 62 m wide, slope up to 20º
Roof type	Aluminium standing seam
Roof sub structure	Halters fixed to top hat rails, to saddles, through liner into purlins
Basic wind speed (hourly mean)	23 m/s
Recorded peak speed (hourly mean)	14 m/s
Design wind suction pressure in damage zone	-2.0 kN/m^2 ↑
Extent of detachment	300 m^2 of standing seam 60 m of parapet capping
Estimated financial loss	£10 million

Table 2: Basic data for Case A

An investigation was commissioned to examine the evidence relating to the wind damage and to identify probable causation. The instructions were received three months after the wind event such that on arrival on site much of the original roof construction and initial damage had been disturbed. Consequently the colour photographs taken immediately after the storm became a vital record. The site inspection confirmed the as-built arrangement of the roof assembly and the details of the fasteners used.

Figure 2: Detachment of aluminium standing seam roofing from windward verge

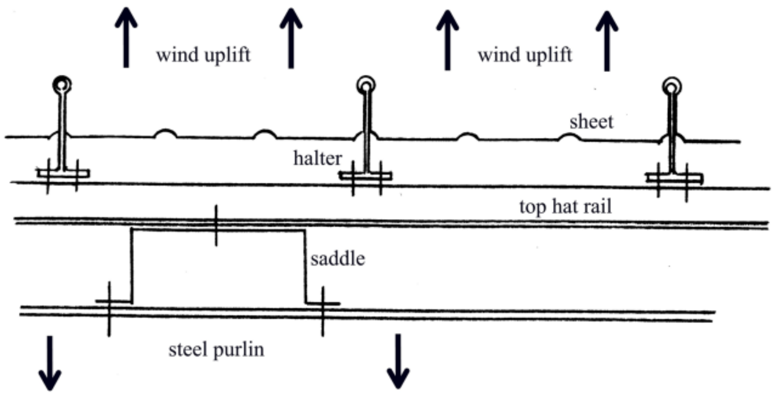

Figure 3: Roof assembly

The wind damage photographs showed that there had been a detachment between the steel top hat rail and the aluminium saddle at 900 mm centres. In addition there was upward distortion in the wide top plate of the saddle. Calculations were prepared to check the strength at each of the connections and the conclusions are summarized in Table 2 below.

<table>
<tr><th>Element</th><th>Material</th><th>Design wind pressure kN/m²</th><th>Area loaded m²</th><th>Number fasteners no.</th><th>Load / fastener w kN</th><th>Fastener strength f kN</th><th>Factor of safety γ</th><th>Satisfactory?</th></tr>
<tr><td>standing seam</td><td>0.9 mm aluminium</td><td rowspan="2">-2.0 ↑</td><td rowspan="2">-</td><td rowspan="2">-</td><td rowspan="2">-</td><td rowspan="2">-5.0 kN/m</td><td rowspan="2">2.5</td><td rowspan="2">✓</td></tr>
<tr><td rowspan="2">halter</td><td rowspan="2">aluminium</td></tr>
<tr><td rowspan="2">-2.0 ↑</td><td rowspan="2">0.64</td><td rowspan="2">2</td><td rowspan="2">0.64</td><td rowspan="2">3.35</td><td rowspan="2">5.2</td><td rowspan="2">✓</td></tr>
<tr><td rowspan="2">top hat rail</td><td rowspan="2">1.25 mm galvanised steel</td></tr>
<tr><td rowspan="2">-2.0 ↑</td><td rowspan="2">1.89</td><td rowspan="2">2</td><td rowspan="2">1.89</td><td rowspan="2">2.1</td><td rowspan="2">1.1</td><td rowspan="2">X</td></tr>
<tr><td rowspan="2">saddle</td><td rowspan="2">2.0 mm aluminium</td></tr>
<tr><td rowspan="2">-2.0 ↑</td><td rowspan="2">1.89</td><td rowspan="2">4</td><td rowspan="2">0.95</td><td rowspan="2">18</td><td rowspan="2">19</td><td rowspan="2">✓</td></tr>
<tr><td>purlin</td><td>10 mm steel flange</td></tr>
</table>

Table 2: Summary of factors of safety for the Competition Pool roof assembly

The calculations found that the local bending stress in the crown of the aluminium saddle was excessive and that the factor of safety against the top hat rail to saddle fixing pulling out was 1.1, significantly less than the recommended minimum of 2.0. This is the same weakest link as observed in the photos of wind damage.

The adjacent verge cappings also became detached in the storm and their means of attachment was closely examined. The aluminium capping had been held in place with rivets which had pulled through. The spacing of the rivet holes through the supporting cladding rail was measured and the distances found to be greater than the recommended 450 mm. This was a further weakness in the roof assembly.

The original roofing contractor undertook to replace the area of detached roofing, to make good the downwind isolated impact damage, and to strengthen the top hat rail to saddle and purlin connection by installing additional long screw fixings through the top hat rail directly into the steel purlin below. This repair scheme had a number of disadvantages, including puncturing the vapour control layer, although those advising the building owners considered the future condensation risks to be acceptable.

3.2 Case study B: single ply membrane roof

On 28th September 2013, St Jude's Day, a fast moving vigorous Atlantic depression brought very strong winds and heavy rain to south east England with winds gusting up to 36 m/s. One modern building that suffered wind damage was a hotel in Chelmsford, to the north east of London. Lengths of roof edging and single ply membrane roofing became detached from the western side of the second floor roof and peeled back, resulting in debris falling to ground level. This led to the closure of the public highway immediately to the east of the building for a period of several days.

Location	Chelmsford, England
Building use	Hotel
Altitude, site exposure, topography	+25 m, sheltered, urban
Roof area	2,000 m^2
Roof slope	Flat
Roof type	Single ply membrane, adhered
Roof sub structure	Mineral wool thermal insulation, screw fixed through vapour control layer into steel deck
Basic wind speed (hourly mean)	22 m/s
Recorded peak speed (hourly mean)	18 m/s
Design wind suction pressure in damage zone	-1.8 kN/m^2 ↑
Extent of detachment	200 m^2 of single ply membrane roofing and roof edges
Estimated financial loss	£1 million

Table 3: Basic data for Case B

An independent investigation of the roof was commissioned two months after the storm to inspect the evidence of damage, to identify causation and to advise on remedial works to remaining roofs. The roof system comprised of a single ply membrane that was adhered to a tissue faced mineral fibre insulation board, which in turn was screw fixed through the vapour control layer into a galvanized steel deck.

Figure 4: Roof membrane rolled back from western edge

At the time of the inspection temporary remedial works had been completed to enable the hotel to re-open. Much of the debris had been removed from site by the repair contractor and fortunately had been kept for examination in his local yard. The samples were closely examined to reveal an inadequate thickness and spacing of the adhesive bonding. Samples of the mineral wool insulation showed that the top tissue facing readily detached from the fibrous core and was not the specified insulation board with a 'single ply adhered facing'. The wrong product had been supplied which had not been identified by the roofing contractor, the supplier or the other surveyors initially inspecting the wind damage.

The wind damage photos also showed that the roof edge became detached. A short parapet had been constructed using two channel sections with an internal metal stud and no fixings joining the channels together. Under wind uplift pressure the capping and support could lift upwards. From this it was possible to determine the probable sequence of detachment along the western edge of the central roof in which a zed section flashing rotated upwards, increasing the wind uplift pressure acting on the underside of the flashing and entering the upstand detail. This in turn caused the perimeter channel and studs to lift upwards, causing the single ply membrane to peel back readily with the lack of adhesive restraint.

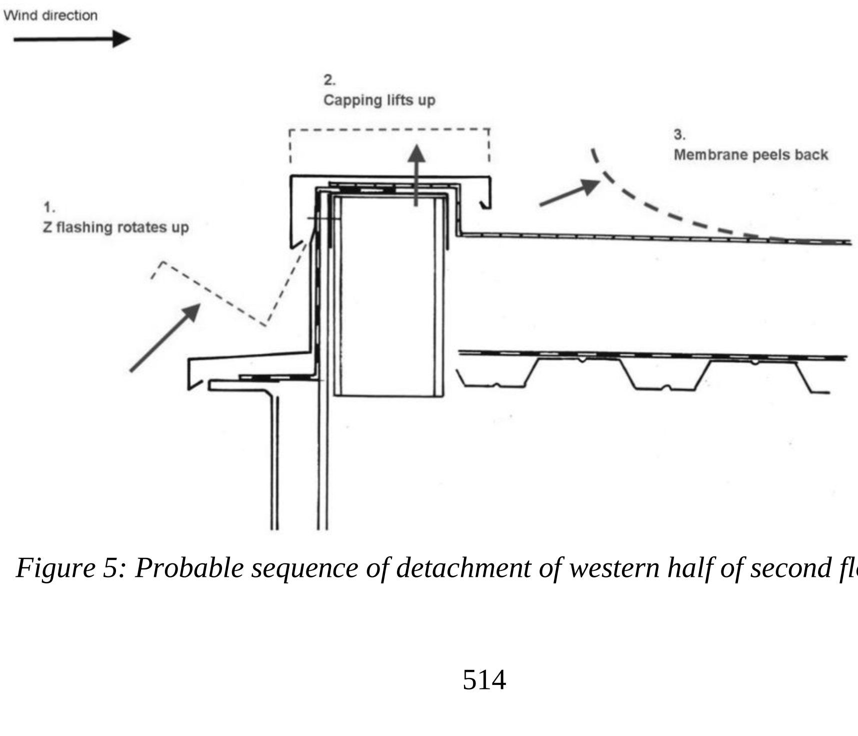

Figure 5: Probable sequence of detachment of western half of second floor roof

Within a month of the initial inspection the second floor roof was fully replaced with a new mechanically attached single ply membrane system. The third and fourth floor roofs were investigated and found to be of a similar construction, with areas of de-bonded single ply membrane adjacent to the western edge. It was recommended that a new mechanically fixed single ply membrane should be laid over the existing with a new secure perimeter detail developed. There were delays in carrying out this work during which the extent of the delaminated zone increased over a six month period, ultimately resulting in extensive ruckling. This evidence of further progressive damage persuaded the parties to mechanically fasten and overlay the third and fourth floor roofs, with works satisfactorily completed in the summer of 2014.

4. Conclusions

Identifying probable causation is rarely straightforward, often with multiple failures requiring an answer to the question 'what failed first?' A methodical approach is needed in gathering and recording the evidence of wind damage, in undertaking the desk study and then producing the factual report.

There is a need to learn from experience and to avoid repeating mistakes. In February 2014 the roof of another aquatic centre in southern Ireland blew off, suffering the same mode of failure as the aquatic centre in Dublin a decade before. The lessons from previous investigations had not been shared within the roofing community.

In the UK the Standing Committee on Structural Safety has established a scheme to improve structural safety and reduce failures by using confidential reports to highlight lessons that have been learnt, to generate feedback and to influence change.

It is hoped that by sharing feedback from wind damage reports in an independent and constructive way we can improve our common understanding of failure mechanisms, enabling us to design and build more reliable building envelopes that are better able to withstand the extremes of changing weather patterns in whichever country we practice.

Abstract

In seismic-prone areas, post-event operability for steel warehouses can be considered an important issue for economic and social continuity during the recovery phase. Structures surviving strong earthquakes - even if designed with minimal probability of collapse - might suffer so much damage, that their repair costs would be prohibitive. Strategies for limiting the building's damaged zones to specific parts (or "fuses") can significantly reduce repair costs. However, the replaceable part is limited to a small portion of the structure, whereas the rest cannot be disassembled in a non-destructive way. This is an issue for steel warehouses, as their life span is more likely dependent on economics and technology rather than on their actual structural performance. From a sustainable design standpoint, making steel warehouses easily disassembled would be cognizant of their environmental footprint, not only in seismic areas but also in any industrialized area The aim of this paper is to explore the Design for Disassembly (DfD) approach to complement seismic design and to find a compromise between these two rather opposite approaches. Due to the complexity of this problem, one single type of structures was analysed (the moment resisting frame), focusing on the design of a seismic-resistant steel connection, capable of being deconstructed in a reversible way. The design process involved several design iterations until an “optimum” compromise between seismic design and DfD was met. It is worth noting that the assessment criteria for seismic design and DfD were different: the former required the compliance with building codes for each connection components; the latter implied to create new criteria, which had to be as accountable as possible. The results of this study show that a compromise between seismic design and DfD is possible. In this specific case, the compromise was achieved at the expenses of more complex design calculations and a number of components larger than that used in standard connections. However, this would be compensated for by a higher residual value for the entire structure. Moreover, this study has proved that a metric for assessing DfD steel connections is possible, but further structural analyses are needed to validate it.

Keywords: design for disassembly, sustainable structural design, reuse of steel structures

1. Introduction

Sustainable design as a research topic involves a wide range of disciplines. Since the development of one of its most commonly accepted definitions - in the “Brundtland Report” in 1987 – research on sustainable has increased significantly and expanded from general areas (i.e. construction sector) to specific fields (i.e. structural design). Studies aimed at investigating the impact of structural systems independently from the rest of the building (Cole and Kernan, 1996) stimulated research on sustainable design of structural systems – the so-called “Sustainable Structural Design” or “SSD.” Research papers pointing out the importance of teaching sustainability in Engineering Schools (Maydl, 2004 and Ochsendorf, 2005) raised attention on the responsibilities of civil engineers towards the environment, economy, and society.

Most of the discussions on SSD involve proper selection and usage of structural materials, as their extraction, manufacturing process and erection can be very carbon and energy intensive. Moreover, growing concerns about the depletion of raw materials (e.g. stone, iron, and bauxite), as well as construction and demolition waste management issues, encouraged researchers to develop SSD strategies. Some of them include “Minimizing Material Use, Minimizing Material Production Energy, Minimizing Embodied Energy, Life-Cycle Analysis/Inventory/ Assessment, and Maximizing Structural Systems Reuse” (Danatzko and Sezen, 2011).

Research projects carried out in countries using large quantities of structural steel (e.g. the United Kingdom) attempted to develop strategies for making the use of steel “greener.” The “Wellmet2050” project, carried out at the Cambridge University, identified four main themes to reduce the steel carbon footprint: “Reuse without melting”, “Less metal, same service”, “Longer, more intense metal use”, and “Supply chain compression” (Allwood et al, 2012). All these strategies aim allow reducing the use of new steel or the energy required to produce it. This translates into structural engineering design practises including the reuse of existing steel (without re-melting it), the optimization of steel profiles in order to use less steel, and the extension of steel structures’ design life by designing structures for future reuse. This paper focuses on this last strategy – also called “Design for Disassembly” or “DfD” – whose main benefit is to overcome the limits of traditional demolition, by obtaining valuable salvaged structural materials instead of scrap or debris (Crowther, 1999). This can be possible by considering a building structure as a kit of components and planning upfront all its assembly and disassembly steps.

Through a set of reversible operations, DfD can also facilitate the substitution or repair of damaged structural profiles. This feature simplifies not only regular retrofit operations but also a structure’s repair after hazardous events. In fact, if structural components are designed properly, those being damaged can be easily disconnected and repaired or substituted. This is a relevant benefit especially for buildings of “normal importance” such as steel warehouses. Yet, even if these structures are designed to withstand strong earthquakes with minimal probability of collapse, they usually suffer a high level of damage and, far too often, repair costs are so prohibitive that demolition is preferred. By reducing repair costs and facilitating the substitution of damaged components, DfD can provide a faster recovery from hazardous events.

Despite its great potential in achieving sustainable and resilient structures, DfD tends to be in conflict with current seismic-design practices, especially as far as concerns the design of connections. In fact, seismic-resistant connections can be barely disconnected in a reversible way, as they usually employ a large amount of connectors to provide adequate strength and stiffness. This practice is at odds with any reuse strategy.

The goal of this work is find a compromise between current seismic design practises and DfD, in order to ensure both post-earthquake reparability and ordinary deconstruction for industrial building. This work will focus on the critical aspect of connections design, with the following goals: a) to design a connection fulfilling both requisites for seismic resistance and deconstruction; b) to develop DfD criteria to assess if the goal is met.

2. Methodology

The design of a DfD seismic-resistant connection is a complex task, as it involves two quite distinct processes: a) the design of a steel connection for disassembly and b) the design of a seismic-resistant steel connection. Process a) is not supported by building codes but its achievement is rather predictable. In fact, construction experience shows what practices should be avoided and which ones should be reduced as much as possible. Conversely, process b) is regulated by codes, but its achievement needs to be proved by numeric analyses and testing. Besides being rather different, processes a) and b) tend to be in conflict, as mentioned in the Introduction.

In order to find a compromise between them, the connection design has been split into two phases. The first phase consisted in the conceptual design of a connection meeting both seismic and DfD goals and in the definition of criteria for a DfD steel connection. The second phase entailed the engineering design and the connection characterization, in order to provide the moment-rotation curves associated with the connection connecting a specific range of profiles. The first phase was carried out at The Catholic University of America and is the object of this paper, while the second phase is still on going.

More in detail, Phase 1) comprised a review of existing steel connection (paragraph 3), a selection of a structural layout in order to define the size of the profiles to connect (paragraph 4), and the actual design. This last phase consisted into two iterative processes, which started in parallel: on the one hand, the definition of criteria for DfD steel connections, and, on the other hand, the design of a connection meeting both these criteria and structural requirements.

Criteria for DfD were initially drafted based on the literature on DfD; these criteria were then refined through a survey (paragraph 5) to a group of "experts" (structural engineers with an expertise on DfD), where they were asked to evaluate some design concepts with these criteria. Eventually, experts were asked to grade and rank those criteria The outcome of this process led to the definition of general criteria to guide the following design iterations and of quantitative criteria for a final design evaluation. After many design-feedback iterations (paragraph 6), a final version of the "pre-design" roughly meeting structural requirements and DfD criteria was developed (paragraph 7) and eventually compared to existing seismic-resisting steel connections on the basis of such those quantitative criteria (paragraph 8).

3. Review of existing steel connections

A review of several steel connections (both traditional and innovative) helped identify the main features of DfD steel connections and seismic-resistant steel connections. The following sub-paragraphs will summarize this review, focusing on beam-to-column connections.

3.1 Traditional steel connections

Generally speaking, steel connections can be located either at the nodes of a structure or along structural members; depending on their structural behaviour, they can be simple, rigid, or semi-rigid; lastly, they can use welds and/or bolts. These very basic features do affect the disassembly potential of connections. In fact, connections placed at structural nodes can make the disassembly process complex, as their removal might compromise the structural stability. Simple connections are usually easier to disconnect than rigid or semi-rigid connections because they employ fewer connectors. Last, but not least, bolted connections can be removed in a reversible way, that is, without destructive operations. On the contrary, welded connections need to be destroyed, for instance by torch cutting. Figure 1 shows some of the most common types of beam-to-column steel connections.

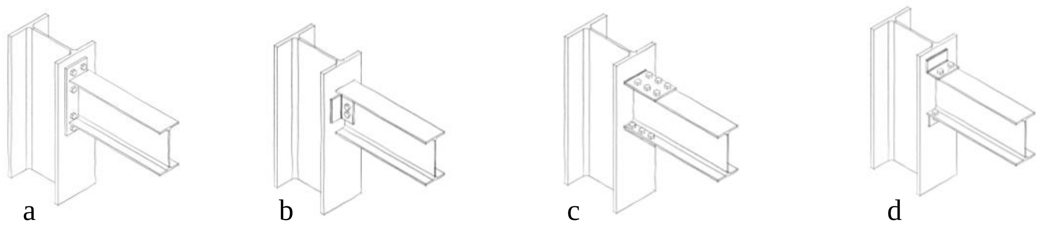

Figure 1: Traditional beam-to-column steel connections: a) extended end plate; b) double angle; c) flange plate; and d) seat connections).

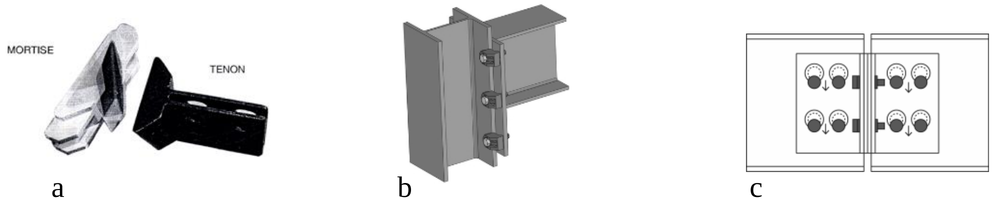
Depending on their assets, steel connections require different degrees of accuracy for their assembly and disassembly processes. For example, being a field-bolted connection, the end plate connection needs that pre-drilled holes on the end plate match perfectly those on the column flange. Other connections, i.e. a double angle connection, may determine assembly issues such as the “knifing” of a beam, that is, the beam coping is needed to lower a beam into place. Eventually, connections, such as a flange plate connection, require tolerances, as a beam needs to fit the distance between the two plates that are shop-welded to a column flange. From a structural standpoint, both an end plate connection (in their extended version only) and a flange plate connection are moment resisting, while double angle and seat connections are can resist shear only.

3.2 DfD steel connections

DfD steel connections employ innovative technologies to facilitate both the assembly and the disassembly processes, in order to increase structural members’ reusability. Figure 2 shows three examples of DfD steel connections. Information on them has been taken from Cooper (2010) and relevant websites (see References).



a b c

Figure 2: DfD steel connections: a) ATLSS; b) LINDAPTER; and c) QUICON connections.

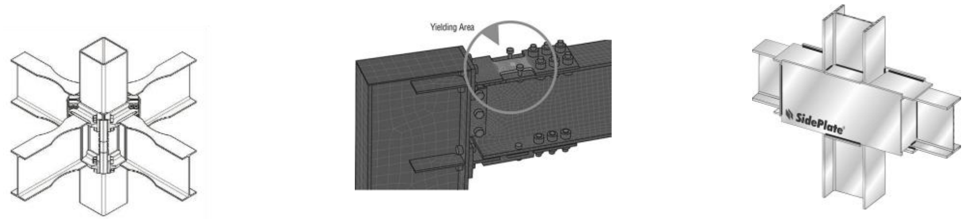
The ATLSS Connection (Lehigh University) comprises two cast pieces shaped to match each other: a tenon – both bolted and welded to the end of a beam - and a mortise welded to a column. In the erection process, the tenon is lowered into place and bolted with one bolt only. A limitation of this connection consists in the fact that shaped cast pieces are barely detachable from structural members and too non-standard to be reused in other structures.

Lindapter (Lindapter GmbH) beam-to-column connection employs "High Slip Resistance Clamps" to keep elements connected. Relying on friction only, this system avoids drilling holes in structural members, thereby maximizing their reusability. However, its moment-resisting application requires welding an endplate and a stiffener to a beam, so that the reuse benefits are limited to columns.

Quicon (Steel Construction Institute) comprises T-stub shop-bolted to a column's flange with k-holes slots on their other free terminal. Shoulders bolts pre-attached to a beam's web are lowered easily in the holes and tightened. This system allow speeding up the assembly process. Boltholes in structural members are the main barrier to reuse. Because of their structural weaknesses, all these connections are currently unsuitable for seismic applications.

3.3 Seismic-resistant steel connections

Seismic-resistant connections are designed to guarantee adequate strength and ductility in the case of seismic events. Some of them dissipate energy through specific components - called "fuses" - that are replaceable. Figure 3 shows three examples of seismic resistant steel connections. Information them has been taken from Cordova (2011) and relevant websites (see References).



a b c

Figure 3: Seismic-resistant steel connections: a) ConXL; b) Strong Frame Yield-Link; and c) SidePlate connections.

ConXtech's ConXL moment connection (ConXtech Space Frame Systems of Hayward) comprises a column's and a beam's "collar" with tapered terminals that should facilitate the erection process. Both the collars are shop-welded to structural members and mutually field bolted. Collars are expected to exhibit minimal yielding, while the Reduced Beam Sections (RBS) to lead to the formation of flexural hinging. From a DfD standpoint, this system presents some disadvantages, including a large number of bolts, which makes the disassembly operations long, the tapered terminals that limit structural members' reusability, and the possibility of using a single type of columns (HSS columns). Moreover, in the case of a fuse replacement, the entire beam should be removed.

Strong Frame Yield-Link™ (Simpson Strong-Tie Company Inc.) is entirely field-bolted. Its reduced-section plate, placed on a beam's top flange, is expected to dissipate energy during an earthquake and is designed to be replaceable. Despite its flexibility, this system uses a large number of bolts, which make it less reusable.

Sideplate (SidePlate) comprises a welded connection, with horizontal shear plates shop-welded to column flanges. The beam is lowered between the plates and welded to them. This solution avoids the formation of a plastic hinge at the beam-to-column interface by physically separating a beam end from a column face; however, its fuse is barely replaceable and its welds are almost impossible to detach.

4. Structural layout selection

Structural pre-requisites for a connection depend on the structural layout and structural elements connected. The moment resisting frame (MRF) was selected among those suggested by the Eurocode 8 because it has an inherent DfD potential. In fact, its lack of vertical bracings confers a great floor plan flexibility. This allows focusing on the connection issue.

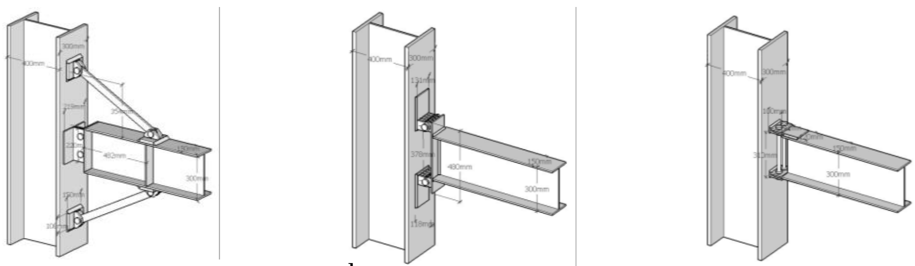
Some important issues to consider in MRF connections design are: a) columns shall be stronger than their adjacent beams, so that the beam fails before the column; b) beam-to-column connections shall be moment-resting to guarantee structural stability; c) the connection must not fail, therefore the connection's shear and moment capacities shall be higher than the beam's shear and moment capacities; d) the seismic "fuse" shall be located as far as possible from the column, so that the risk of column failure is avoided.

The steel profiles to be connected were sized on the basis of common spans and widths for one-story one-bay steel industrial buildings (determined from previous research works): an IPE 300 section for the beam and a HEA 400 section for the column.

5. Surveys

In order to find a trade-off between structural prerequisites and DfD, a priority among DfD criteria should be determined. Criteria for DfD were initially listed based on the review of steel connections; then, these criteria underwent an examination from a group of "experts" (civil engineers/architects with an expertise on DfD), in the form of a semi-structured survey. This survey consisted in three sections: 1) an introduction; 2) a presentation of three connections designs, which the group of experts should evaluate on the basis of the listed DfD criteria; and 3) a section in which experts were asked to rank the importance of these criteria, by means of a “Likert Scale” (from Strongly Agree to Strongly Disagree).

Since the survey was an online-survey expected to take a limited amount of time, criteria for DfD were kept under the limit of seven criteria: 1) “Reduce the number of bolts” (with respect of traditional connections): the smaller the number of bolts to unbolt, the faster the disassembly process is; 2) “Use the same type of bolts”: the fewer the disassembly tools, the faster the disassembly process is; 3) “Adaptability of different structural members”: the more adaptable, the more reusable the connection is; 4) “Reduce the holes in the structural members”, increasing their reusability (too many holes require patching the holes – when not cutting off the bolted part); 5) “Ease of access for the disassembly operation” (a non-accessible connection cannot be disconnected at all); 6) “Reversibility”, so that the disassembly produces no or limited damage; 7) “Ease of assembly” (so that DfD and assembly are not in conflict). These criteria served to evaluate three design concepts (Figure 4) in terms of reusability and disassembly potential with respect to common beam-to-column moment resisting connection. It is worth noting that one inherent limit of this evaluation is the fact that there is no unique understanding of what a common moment resisting beam-to-column connection is; yet, the evaluation was deemed reliable purely on the basis of an the experts’ personal judgement.



a b c

Figure 4: Preliminary design concepts (design idea #1: diagonals; design idea #2: many shear plates few bolts; design idea #3: two long bolts)

In about one month, six experts took the survey providing an evaluation of both the design and of the DfD criteria. These surveys had two main outcomes: design idea #1 (Figure 4, on the left) turned out to be the best one under all the criteria; a general agreement on the criteria raking was not found, and this led to the conclusion that criteria should be refined so that they could be used as transparent tool.

6. Design iterations

Surprisingly, the most useful part of the survey was the section in which experts were asked to give an open feedback on the design. This helped identify design ideas strengths and weaknesses and guided following design iterations. Some of the interviewed experts offered to keep on providing feedbacks on new design ideas. Interestingly, DfD goals for the connection emerged naturally from this iterative process and can be summarized as follows: to avoid welds, to reduce bolts, and to be adaptable to different steel profiles.

7. Final design

The design process stopped when, in proximity of the end of the time available, the overall goal of avoiding welds and holes in structural members was met. Even if this paragraph is called “final” design, the design process did not stop there. During the second phase of this work, the design changed, even if these changes are not addressed in this paper. At the end of first phase, the connection incorporated some of the ideas developed at the very beginning of the conceptual design process: a) the use of clamps to avoid bolts and welds in structural members; b) the use of external connectors; and c) the increase of the number of section planes to reduce the amount of bolts. Among the three design concepts, the connection layout resembles design idea #1 the most: two diagonals deliver bending moment to a column, while a “shear tab” bears the gravity loads.

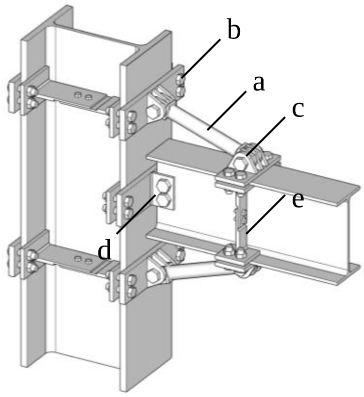


Figure 5: Final design

All the connection components were sized according to Eurocode 3 and 8. More in detail, these components are: a) two diagonals; b) slip-critical clamps; c) pins; d) a shear tab; and e) continuity plates. The diagonals serve to increase the moment arm, in order to reduce the entity of the horizontal forces applied to structural elements. The diagonals are also conceived as replaceable “fuses”. Therefore, they are designed with a lower steel grade (S235) than the rest of the structure (S275) so that they reach their yielding point before. The diagonals’ cross section is a tubular with a great thickness in order to impede buckling phenomena. The clamps serve to avoid boltholes and welds on structural members. High strength slip-critical bolts are used for this purpose. The condition upon which the clamps work properly is that the steel plates do not bend. To ensure it, steel plates are thick and stiffened by the steel plates forming the pins. The pins connect the clamps to the diagonals; they consist in a row of shaped plates that increase the number of shear planes, thus reducing the overall number of bolts. The “shear tab” is clamped to the column and bolted to the beam. These two boltholes at the beam end were considered an acceptable compromise, considering the fact that the beam web might have to accommodate another shear tab in future re-uses. The continuity plates are welded to the clamping plates and are secured through slotted holes. They are used instead of stiffeners - which are usually welded to the beam's and column's webs - and are meant to receive a portion of the vertical load off the beam's web.

8. Discussions

The main challenge for this design was to keep all the bolts and the welds of connection outside the structural members (with the exception of two boltholes on the beam web). This translates into two major benefits: the acceleration of both the assembly and the disassembly processes and a high degree of reparability/flexibility/reusability. Figure 6 synthetizes the first advantage: since most of the construction processes are carried out off-site, the erection can be faster and more accurate.

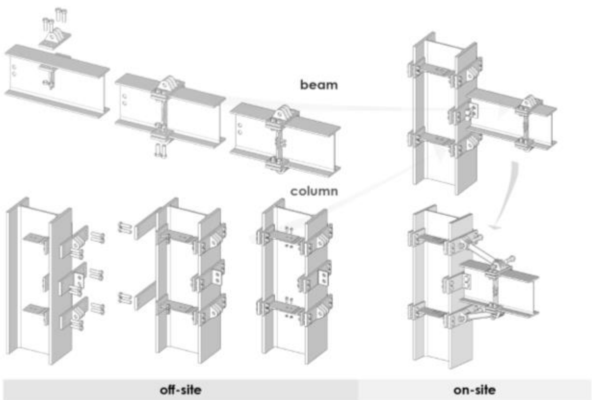

Figure 6: Construction operations

Figure 7 shows the second advantage. The substitution of damaged diagonals requires unbolting four bolts only. A minor change in the configuration requires unbolting more bolts but should be a very reversible process. If the entire system were disconnected, steel profiles would be easily reusable. Two other interesting advantages for this connection are its applicability to a variety of building structures (not only the industrial ones) and its potential for being a retrofit measure: the diagonals and the clamp system can be inserted in any existing connection to improve its moment capacity in a reversible way.

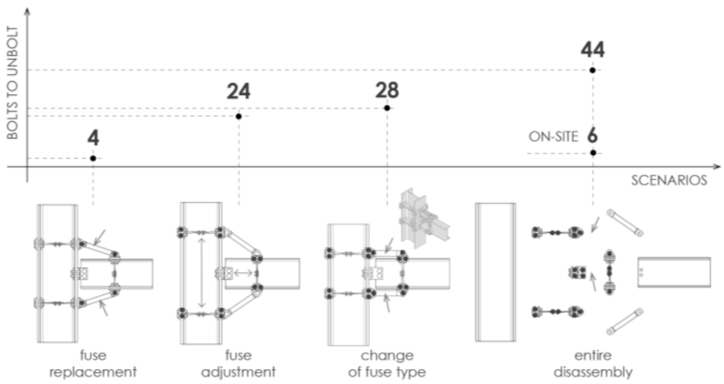

Figure 7: Reuse scenarios

Despite these relevant benefits, this design presents some issues. First, this connection is overall more complex than most of the other existing connections and employs more material. Secondly, this connection is likely a semi-rigid connection rather than a rigid connection, which puts some restriction to its use. However, all these drawbacks can be compensated for by a high residual value for steel profiles at a structure's end-of-life.

In order to evaluate if the goal of designing a seismic-resistant connection with a higher disassembly potentials than the existing ones, a new set of DfD criteria was developed. These criteria are an improvement of those used in the surveys, are accountable and fewer (four criteria), making the evaluation simple. Figure 8 shows a comparison between the design and two existing seismic-resistant steel connections, based on new DfD criteria: number of bolts to be assembled or disassembled on-site; number of holes in the structural members; length of welds in the structural members; ability of replacing the seismic fuses.

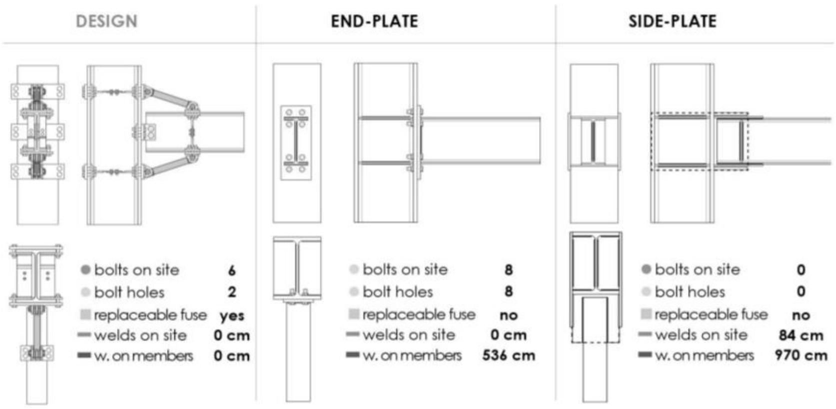

Figure 8: Comparison with a traditional and an innovative seismic-resisting connection

The existing connections were assumed to have the same capacity of the design connection and their capacity values were taken from the following literature: Ardeshir and Ashraf (2004) provided values for the end plate connection, while Dessouki et al (2013) for the side plate connection. It is worth noting, though, that the real capacity for the design connection was not determined yet and its design value was taken as the value of the connection capacity. As one can see from Figure 8, the design and the end plate connection have a similar number of bolts to be bolted (or unbolted on-site). However, the design entails a higher degree of reusability for the structural members because it is weld-free, has two bolts only and a replaceable fuse. Conversely, both the end plate and the side plate connections turn to be not as easily reparable (their "fuses" cannot not be easily replaced), reusable (either too many boltholes or too many welds) and reversible (the welds cannot be removed in a reversible way).

9. Conclusions

The results of this investigation show that, despite their evident conflict, seismic design and DfD can be combined to reach innovative solution. In this case, the compromise of having a DfD seismic-resistant connection implied complex design calculations and many connection components. However, this would be compensated for by a high residual value for the steel members, a potential waste reduction, and energy savings. This study has also demonstrated that it is possible to develop a metric for assessing DfD steel connections, but further structural analyses are needed to validate it. In fact, in order to compare the DfD potential of two connections it is necessary to know their real structural performances. This part is currently on going will be presented in future research papers.

The Experimental Behavior of CFRP-Strengthened Reinforced Concrete Slabs with Fire Protection Systems Subjected to Standard Fire Exposure

Saeed Bakhtiyari, Arsalan Kalali, Leila Taghiakbari and Farhang Farhbod

Road, Housing & Urban Development Research Center (BHRC), Iran
Email: bakhtiari@bhrc.ac.ir

Abstract

Fire resistance of CFRP (carbon fiber reinforced polymer) strengthened concrete slab systems were evaluated in two forms of unprotected and protected against fire. In order to achieve this objective, an unstrengthened and two CFRP strengthened concrete slab (totally 3 specimens) were firstly subjected to increasing gravity loading until failure. The test results revealed that CFRP strips bonded to concrete slabs increased the load-bearing capacity considerably. So, this method can be suitable for flexural strengthening of concrete slabs. Subsequently, the unstrengthened concrete slab was placed on a furnace and was subjected to a constant service gravity load and then, the temperature of the furnace was increased according to a standard temperature-time curve until the failure of the slab occurred. This concrete slab was strengthened by CFRP with two different amounts and then, in two cases of unprotected and protected against fire (two different thicknesses) were tested with aforementioned method (totally 4 specimens). The results showed that because of more load-bearing capacity and subsequently increase in service gravity load, the strengthened concrete slab failed in a short time due to the lack of CFRP resistance against the fire. By contrast, the protected specimens resisted the fire in a considerable time. In addition, it was revealed that details of fire protective coating had an important effect on fire resistance duration and in flat large surfaces with thick fire insulation, the use of reinforcing mesh must be considered.

Keywords: reinforced concrete slab, strengthening, FRP, fire protective coating, fire resistance

1. Introduction

Fiber reinforced polymers (FRPs) are mainly used in civil engineering because of their advantages such as high resistance, light weight, and resistance against corrosion compared to available materials. Carbon fiber reinforced polymer (CFRP) strips are composite materials that currently used as external strengthening bonded to reinforced concrete members with epoxy resins (Hollaway 2010).

Although CFRP system has considerable advantages in concrete buildings, there are concerns about its behavior in high temperatures. In fact, the stiffness and resistance of FRP greatly decrease in relatively low temperatures (Dodds et al. 2000; Correia et al. 2013), i.e. when temperature reaches glass transition temperature (T_g) of polymer matrix that usually lies between 55 to 120 °C. Also, the bond strength between CFRP and concrete which is necessary for the effectiveness of the strengthening system is severely reduced in temperatures higher than T_g. Some researchers have showed that the bond strength between CFRP and concrete rapidly decreases, if the temperature of the epoxy resin increases to more than about 60-70 °C (Gamage et al. 2006; Leone et al. 2009; Ahmed and Kodur 2011a).

Fire resistance tests performed on CFRP strengthened reinforced concrete beams (Williams et al. 2008; Ahmed and Kodur 2011b; Palmieri et al. 2012), slabs (Williams et al. 2006; Lopez et al. 2013), and columns (Bisby et al. 2005; Chowdhury et al. 2007) revealed that when temperature of epoxy resin reaches T_g, composite action between CFRP and concrete will be weakened.

External strengthening using FRP composites are performed in various structural reinforced concrete members. Generally, external strengthening system with FRP sheets is used for three main objectives of flexural strengthening, shear strengthening, and confinement and increase in ductility of compressive members. Considering the subject of this study, flexural strengthening of reinforced concrete slabs using CFRP strips was only investigated here. When CFRPs are used in buildings for the retrofitting of reinforced concrete (RC) slabs, FRP-strengthened RC slabs have to satisfy fire resistance requirements specified in building codes. Thus, conducting fire tests on FRP-strengthened RC slabs is necessary to generate fire endurance ratings and study the response of them under fire conditions. In addition, there was a lack of data on FRP-strengthened slabs protected with domestic fire insulation system used in this research project.

First of all, a reinforced concrete slab is designed and then it is strengthened by CFRP strips. Subsequently, the fire resistance of reference concrete slab, CFRP strengthened concrete slabs as well as CFRP strengthened concrete slabs and protected by fire protective coating will be evaluated in a furnace according to the standard test method.

It should be noted that in the present study, only external strengthening of concrete slabs by CFRP materials has been investigated and internal strengthening by elements such as FRP bars has not been taken into account. Selection of carbon fibers in strengthening of concrete slabs was due to their high ratio of resistance to weight and widespread use of them in strengthening of different concrete structures. On the other hand, it should be considered that the amount of creep in carbon fibers is very low in comparison with glass fibers and so, they are more suitable for strengthening of concrete slabs against gravity loads (Hollaway 2010).

Also in this research, mechanical properties of materials used in the concrete slabs such as compressive strength of concrete and tensile strength of steel bars were determined according to the standard test methods.

2. Experimental Program

2.1 Design of test Specimens

In order to examine the fire resistance of CFRP strengthened concrete slabs as well as the performance of fire protective coatings, a total of 8 concrete slabs were fabricated as shown in

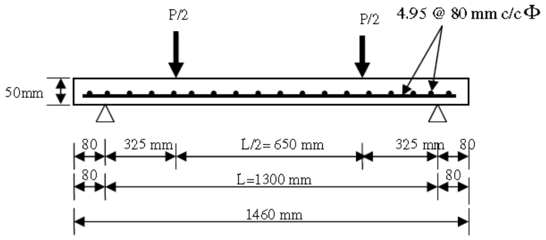
Table 1 at Road, Housing & Urban Development Research Center (BHRC). Test specimens were designed and made by considering the following parameters:

1. The effect of strengthening with CFRP; 2. Test temperature (room temperature as reference and exposure to furnace conditions for evaluation of fire resistance); 3. Width of strengthening strips; 4. Thickness of fire protective coatings.

Table 1: Specifications of test specimens

Row	Slab designation		Without strengthening	Strengthening with two one layer longitudinal CFRP strips		Without fire protective coating	With fire protective coating	
				30 cm width	15 cm width		2.6 cm thickness	1.6 cm thickness
1	Exposure to room conditions	CS-25	✔			✔		
2		FR1-25		✔		✔		
3		FR2-25			✔	✔		
4	Exposure to furnace conditions	CS-Fire	✔			✔		
5		FR1-Fire		✔		✔		
6		FR1-Fire-P1		✔			✔	
7		FR1-Fire-P2		✔				✔
8		FR2-Fire			✔	✔		

Because of existing dimensional limitations, the test specimens were scaled by scaling factor of one-quarter and fire resistance tests were performed in a one cube meter (1 m^3) furnace. Thickness, width, and length of these small-scale specimens were 5, 98, and 146 centimeters, respectively. Reinforced concrete slabs in two cases of unstrengthend and strengthened with GFRP, were designed as per ACI 318 (2011) and ACI 440 (2008) provisions. Test details including specimens dimensions, load places, and supports in two cases of unstrengthened and strengthened, are illustrated in Figures 1 and 2, respectively.



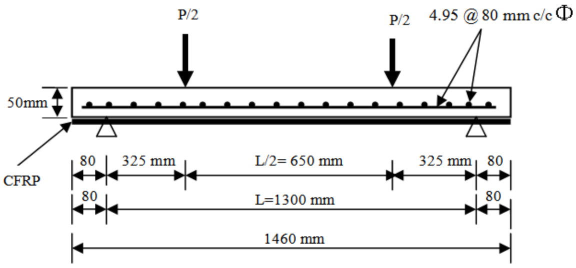


Figure 1: Geometrical properties of unstrengthened slabs and reinforcement details

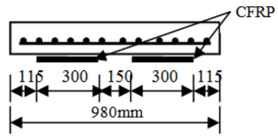

Figure 2: Geometrical properties of strengthened slabs with two one layer longitudinal 300 mm wide CFRP strips

As it is shown in these figures, the free length of flexural slabs is equal to 130 centimeters. As the specimens were scaled, tensile steel of the slabs was formed of a welded reinforcing bar mesh with a diameter of 4.95 millimeters and a distance of 8 centimeters from each other in both directions. For the case of unstrengthened concrete slabs, the section was low steel and so, the mode of flexural failure was ductile. In this case, firstly steel begins to yield and then, crushing of concrete in compression zone occurs. Also, for the case of CFRP strengthened concrete slabs, the amount of CFRP was selected in a manner to achieve tensile yielding of steel in flexure which is desirable and ductile. Namely, the tensile steel is yielded at the first time and then, crushing of concrete in compression zone happens before the rupture of CFRP strips.

2.2 Materials

2.2.1 Concrete

In order to make concrete for slabs, Portland cement type 1 and standard sands and gravels were utilized. Compressive strength of cylindrical concrete samples at 28 days age and on the day of the fire resistance test (6 months age) was 16 and 20 MPa, respectively. The mentioned data are the average of compressive strength of three samples for each time of test. The compressive strength of cylindrical samples was determined according to ASTM C 140 (2011).

2.2.2 Steel

With respect to scaling test specimens, welded wire mesh was used instead of reinforcing bars in concrete slabs. In order to determine mechanical characteristics of steel reinforcement used in construction of concrete slabs, one direction simple tensile test was performed on raw and welded steel wire samples according to ASTM A 370 (2011) and obtained results are given in Table 2. It is obvious that welding causes strain hardening, decrease in fracture strain, and increase in tensile and yield strength of the steel. Also, at the end of the tensile test of welded steel wires, it was observed that the fracture of samples did not occur at the welded locations.

Table 2: Mechanical properties of raw and welded steel wire samples

Sample	Wire type	Diameter (mm)	Yield strength (kg/cm^2)	Tensile strength (kg/cm^2)	Fracture strain (%)
1	raw	4.95	4158	5719	19
2	raw	4.95	4211	5823	18
1	welded	4.95	5700	6400	13.6
2	welded	4.95	5580	6800	12

2.2.3 CFRP

Carbon fibers together with epoxy resin were used to strengthen the concrete slabs. So, the composite material resulted from this mixture is a kind of CFRP composite which was applied for strengthening six reinforced concrete slabs. Geometrical and mechanical characteristics of this type of carbon fiber with commercial name of PANEX are presented in Table 3 based on specifications announced by the producer.

Table 3: Geometrical and mechanical properties of carbon fibers used in the study

Density (g/cm^3)	Thickness (mm)	Elastic modulus (GPa)	Tensile strength (MPa)	Elongation at break (%)
1.81	0.176	242	4127	1.5

2.2.4 Fire protective coating

The surface exposed to fire (bottom surface) of two slabs was protected by sprayed fire protective coating from type of gypsum-vermiculite (Vermifire-G) with two nominal thicknesses of 15 and 25 mm. After spray and when coating became dry, thickness in different locations were measured and actual values were 16±2 mm and 26±2 mm for two cases. Also, measured average density was 600 (kg/m^3). These measurements were carried out in accordance with ASTM E 605 (2011). For higher bond strength and according to the producer's instruction, a thin layer of primer was firstly applied on the slab surface. Also, a keying steel mesh was fixed between primer and coating layers when the primer layer was still wet.

2.3 Test setup and instrumentation

In this study, the fire resistance experiments were performed by an intermediate scale furnace (1 m^3) at Road, Housing and Urban Development Research Center (BHRC). In all the tests, the furnace temperature was increased according to the temperature-time curve of BS EN 1363-1 (2012). The mean temperature of furnace was measured by thermocouples installed inside the furnace. During testing, the mean temperature of furnace had been accurately maintained in the standard limit. In all the tests, vertical loading on the specimen was applied by a hydraulic jack statically. Considering the performance type of a concrete slab, fire resistance tests were continued until the failure of load bearing capacity criteria and the comparisons were fulfilled on this basis.

Flexural loading test on eight slab specimens were carried out according to ASTM E 72 (2010). Vertical displacements of each slab were measured by four LVDTs at midspan and support locations. Also, strain at tensile steel of the slab, extreme concrete compression fiber and outside surface of FRP were measured and recorded in each step by installed strain gauges.

For the fire test, the slab specimens were placed on the furnace. Quarter-point loading configuration was selected and two equal loads were applied on the slab specimens, each at a distance of one quarter of the span from the supports, toward the middle of the span. The total load for each specimen was equal to its calculated service load. After loading, when a steady condition (almost zero increase in deflection with time) was reached, the slabs were exposed to fire in accordance with the standard fire curve, with no additional load. The slabs were simply supported at the ends with a total length of 1.46 m, of which 1.3 m was exposed to the standard fire by the furnace. Each slab specimen was supported on an insulated edge along four sides of the furnace which did not make any restraint to the movement of the slab in its free edges. For this purpose, a ceramic fiber blanket insulation was placed between the slab and its supports and the edges of the furnace for the prevention of flame and heat exit (Figure 3). Also, for specimens FR1-Fire and FR2-Fire that CFRP layer did not have any fire resistant material, for protecting the strain gauges installed on the CFRP against the fire, they were covered by a ceramic fiber blanket insulation which was fastened to the concrete slab by means of a steel mesh.

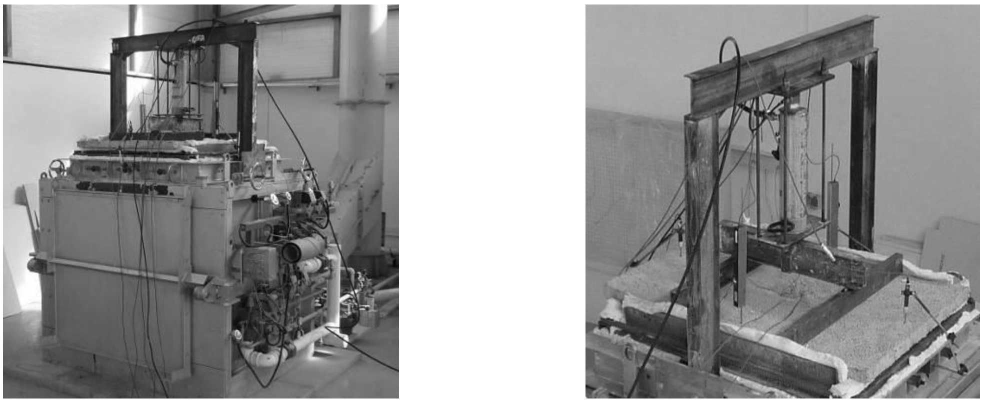

Figure 3: Test setup for the fire resistance tests

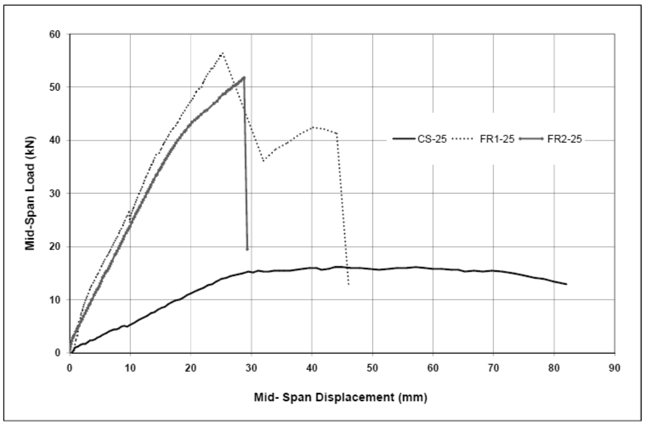
In these fire resistance experiments, two thermocouples were mounted inside each specimen to measure the temperature of the steel mesh (No. 2) and the specimen center (mid-thickness, thermocouple No. 1) at mid-span. In specimens FR1-Fire-P1 and FR1-Fire-P2, two additional thermocouples (No. 3 & No. 4) were places between the CFRP layer and the fire protective layer in order to measure the temperature of the CFRP layer.

3. Results and discussion

3.1 Gravity loading tests

Three slab specimens were tested under gravity loading in room conditions (almost 25 °C). One specimen (CS-25) was unstrengthened and two other specimens (FR1-25 and FR2-25) were strengthened with CFRP. In these tests, the applied vertical load was incrementally increased until the failure of the specimen was reached, i.e. reduction in the specimen strength after experiencing the maximum strength was at least 20%. Obtained load-deformation curve for these specimens is shown in Figure 4.



(a) (b)

Figure 4: (a) specimen CS-25 during testing; (b) Variation of load versus mid-span deflection for specimens CS-25, FR1-25, and FR2-25

In Figure 4, load-displacement curves of specimens CS-25, FR1-25, and FR2-25 are compared. According to this figure, the maximum flexural load-bearing capacity of strengthened specimens FR1-25 and FR2-25 is more than that of unstrengthened specimen CS-25 by a factor of 3.47 and 3.28, respectively, which shows the high efficiency of CFRPs in the flexural retrofitting of concrete slabs. On the other hand, as can be seen in this figure, the strengthening with CFRPs causes a reduction in the assembly ductility; since the stress-strain curve of CFRPs is linear up to failure (CFRPs have brittle behavior).

3.2 Fire resistance tests

A total of five slab specimens in accordance with Table 1 were subjected to fire resistance tests including one unstrengthened specimen (CS-Fire), two strengthened specimens without fire resistant material (FR1-Fire and FR2-Fire) and two fire protected strengthened specimens (FR1-Fire-P1, FR1-Fire-P2). In these tests, firstly the applied vertical load to each specimen was incrementally increased to reach the specimen service load. After loading, the furnace temperature was increased according to the selected standard temperature-time curve until the failure of the specimen occurred, namely the specimen was no longer able to resist the applied constant vertical load.

3.2.1 Specimen CS-Fire

A service load of 9.5 kN was obtained in accordance with ACI 440.2R-08 for the unstrengthened slab, which is corresponding to a stress of $0.8F_y$ in the slab tensile reinforcement, where F_y is the yield stress of the reinforcement. The mid-span displacement-temperature curve for this specimen is plotted in Figure 5. In this test, firstly, the load was gradually increased up to 9.5 kN which the corresponding displacement was equal to 13.5 mm.
After mechanical loading, the specimen was exposed to the standard fire. During the testing, the mid-span displacement of the specimen increased continuously. With the increase in the temperature during the test, a progressive cracking in the slab top surface developed. After the steel mesh temperature reached 550 °C, the slab mid-span displacement became suddenly 123.4

mm and the specimen failure happened. At that moment, the slab residual strength became lower than the applied constant load due to elevated temperatures. The test was stopped at approximately 79 min of fire exposure time because of the failure of the strength criteria. Figure 6 shows the temperature-time curve of the installed thermocouples in the specimen. For analyzing the slab failure at 79 min, the following explanation can be mentioned:

This unstrengthened concrete slab was under a constant load of 9.5 kN during the fire resistance test. Since the maximum load carrying capacity of this slab was 16.15 kN, thus the ratio of load to strength was around 0.6. At the failure time of the slab (79 min), the steel temperature was recorded as 550 °C by means of the installed thermocouple. In this temperature, the yield strength of the steel reaches 0.6 of its initial value in accordance with ANSI/AISC 360 (2010). Therefore, the slab flexural strength decreases about 40% and reaches from 16.15 kN to lower than the applied load of 9.5 kN that causes the slab to fail which agrees with experimental results. It should be noted that since the compression depth of this slab is small, the slab flexural strength is approximately related to the steel yield strength with a linear equation.

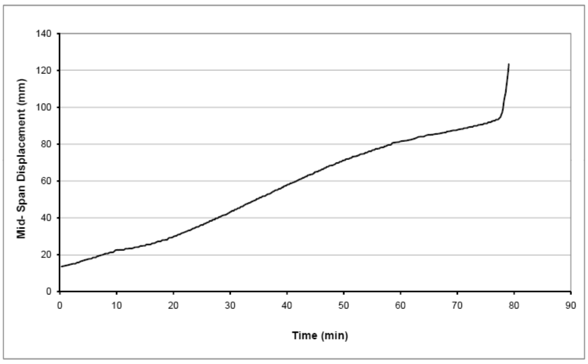


Figure 5: Measured mid-span displacement as a function of fire exposure time for slab CS-Fire

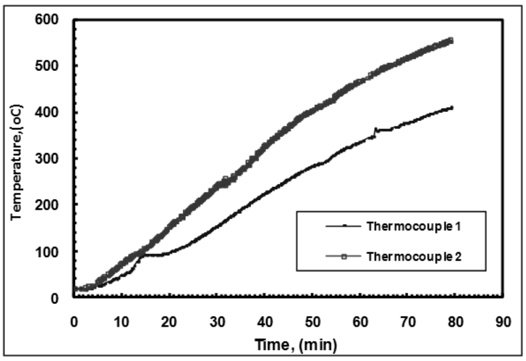

Figure 6: Temperature-time curve of installed thermocouples in slab CS-Fire

3.2.2 Specimens FR1-Fire & FR2-Fire

The service load of the strengthened specimens was computed based on the conditions that the service stress in CFRP sheets reaches $0.33C_DC_Ef_{fu}$ according to ACI 440.2R-08. C_E (environmental reduction factor), C_D (durability factor), and f_{fu} (tensile strength of fibers) were considered as 0.65, 1, and 4127 MPa, respectively. Finally, these service loads for specimens FR1-Fire and FR2-Fire were determined as 33 and 24 kN, respectively.

Variations of mid-span deflection versus time for specimens FR1-Fire and FR2-Fire are plotted in Figure 7. In specimen FR1-Fire, the load was incrementally increased until the calculated service load of 33 kN was obtained and the corresponding mid-span deflection was equal to 31.6 mm. Then, after the start of the fire test, this load was kept constant. With the increase in furnace temperature, the specimen mid-span deflection increased and when its value reached 43.3 mm, the debonding of CFRP sheets from the concrete surface in the fire-exposed span of the slab occurred. Then, anchorage failure and spalling of the concrete under a CFRP sheet in one slab end occurred (Figure 8) that resulted in a rapid reduction in the slab strength and so, the slab failed.

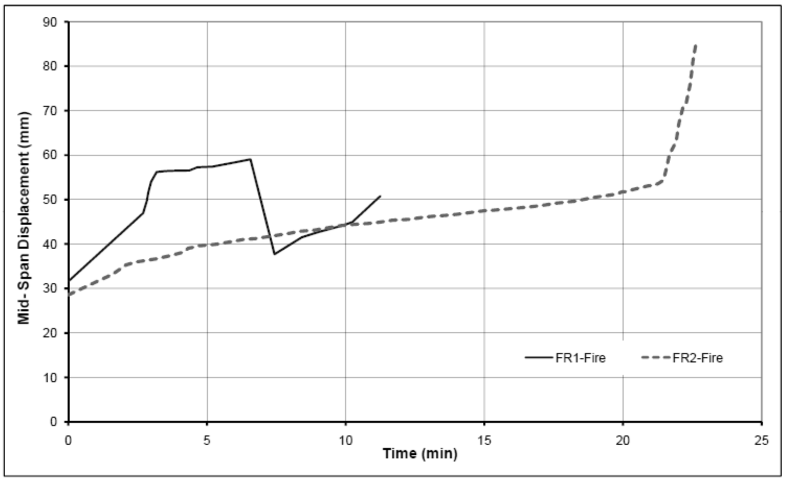

Figure 7: Mid-span deflection as a function of fire exposure time in strengthened specimens FR1-Fire and FR2-Fire without any external fire insulation

This test was stopped at 7 min due to the torsion of the transverse beams which the load was being applied to the slab by them. After the modification of the loading system, the fire test was performed again. After 4 min, the test was terminated because the slab was not able to carry the applied load any more. In other words, the strength of the slab at this time was lower than the applied load due to high temperatures. The fire endurance of this specimen was totally 11 min (Figure 7).

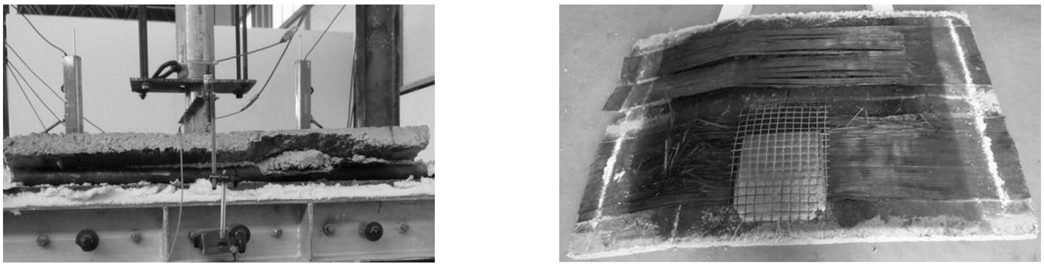

Figure 8: Specimen FR1-Fire at the end of the fire test

Visual observations were made for this specimen after the test. As can be seen in Figure 8, the epoxy resin of the CFRP strips in the fire-exposed span of the slab has burned. However, we can conclude that during the testing, in the absence of any debonding of CFRP within anchorage zones located outside the fire zone, the unbonded continuous carbon fibers at the slab bottom continued to contribute towards the tensile strength of the beam through the cable mechanism. Due to this cable mechanism, the collapse of the slab was delayed until the anchorage failure was reached and thus, the slab fire resistance increased. In practice, the use of mechanical anchors at both ends of FRP can aid the cable mechanism. It should be noted that in the literature, there is a lack of data on the contribution of this cable mechanism to fire endurance of FRP-strengthened slabs without any fire protection system.

It can be seen according to the temperature-time curve of the installed thermocouples in specimen FR1-Fire that the temperature of the steel was low and before reaching 100 °C, the test terminated. This is because the applied load to this strengthened slab was higher than that of the unstrengthened slab, due to the contribution of the CFRP sheets to the slab load bearing capacity. On the other hand, the epoxy resin in the CFRP is very vulnerable to high temperatures and after exposing to the fire, the strength of the CFRP-strengthened slab suddenly diminishes. Thus, FRP-strengthened concrete slabs that the FRP has not any fire protection coating, have very lower fire endurance as compared to that of the unstrengthened case in a fire event.

Similarly, in specimen FR2-Fire, the load was incrementally increased up to the calculated service load of 24 kN and in this situation, the corresponding mid-span deflection was equal to 28.6 mm. Then, after the start of the fire test, this load was kept constant. With the increase in the furnace temperature, the specimen mid-span deflection increased and when its value reached 53.6 mm, the debonding of the CFRP sheets from the concrete surface in the fire-exposed span of the slab occurred that leaded to a significant reduction in the slab strength. Then at mid-span deflection of 85.2 mm, the collapse of the slab occurred.

The fire test of specimen FR2-Fire terminated at 22 min because of the strength criteria failure. In other words, at this time the slab was not able to tolerate the applied load. Overall, the above explanation about the fire behavior of specimen FR1-Fire can be mentioned for this specimen again. However, due to the lower mechanical load in this case, the fire resistance rating and thermocouples temperature for specimen FR2-Fire are higher than those of the previous specimen.

Visual observations were made for this specimen after the test. Similar to specimen FR1-Fire, the epoxy resin of the CFRP strips in the fire-exposed span of the slab has disappeared and the continuous carbon fibers have separated from each other and debonded from the concrete surface in this region.

3.2.3 Specimens FR1-Fire-P1 & FR1-Fire-P2

The mid-span deflection as a function of time for specimen FR1-Fire in two cases of protected and unprotected against the fire is shown in Figure 9.

For the purpose of comparing the results of protected and unprotected slabs against the standard fire, the loading conditions was considered the same and the service load of specimen FR1-Fire (i.e. 33 kN) was applied to fire-protected specimens FR1-Fire-P1 and FR1-Fire-P2 similarly. The loading method for these specimens was similar to specimen FR1-Fire. That is the applied load was incrementally increased up to 33 kN and then, was kept constant during the fire test.

According to Figure 9, the fire test of specimen FR1-Fire-P1 terminated at 47 min due to the failure of the load bearing capacity criteria, that is the strength of the specimen reached lower than the applied constant load of 33 kN. However, the strength criteria failure for specimen FR1-Fire took place at 11 min that indicates the significant positive effect of the fire protective material. The temperature-time curve of the installed thermocouples in specimen FR1-Fire-P1 is plotted in Figure 10.

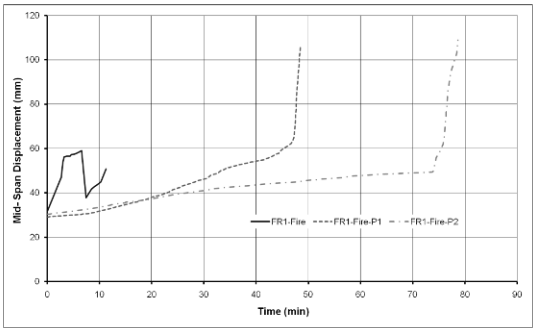

Figure 9: Variations of mid-span deflection versus the fire exposure time for specimens FR1-Fire, FR1-Fire-P1, and FR1-Fire-P2

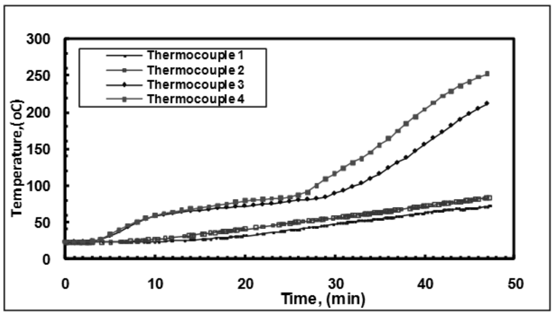

Figure 10: Temperature-time curve of the thermocouples connected to slab FR1-Fire-P1

During the fire test, cracking and spalling of the fire resistant coating of slab FR1-Fire-P1 occurred that leaded to faster transfer of the heat flow to the strengthened concrete slab (Figure 11a). In spite of the higher thickness of the fire insulation in specimen FR1-Fire-P1, the fire resistance of this specimen was lower than that of specimen FR1-Fire-P2 (Figure 9). This was due to the high thickness of the external thermal insulation and unsuitable details. In specimen FR1-Fire-P1, about 2 cm of the insulation was located outside the keying mesh. During the fire test, falling off some portions of the unreinforced protective coating happened as a result of high temperatures and slab deformations (Figure 11a). This phenomenon started at around 28 min and at 47 min reached its peak. Due to this phenomenon, the CFRP was exposed to high temperatures and subsequently, the CFRP failed and it caused the specimen to collapse rapidly. This event demonstrates that the details of fire protective coatings have important role on their performance and an increase in the insulation thickness without appropriate details can accelerate the spalling of the insulation and weaken the fire protection effectiveness. According to BS 8202-1 (1995), for high thickness insulations and or large flat substrates, the use of reinforcing mesh into the insulation may be required for providing integrity. However, where the insulation is locked in position by virtue of the shape of the element, for example I shape columns, the reinforcing mesh is not usually needed because of the encapsulation by the insulation.

(a)  (b)

Figure 11: (a) Cracking and spalling of the fire protective coating in specimen FR1-Fire-P1 at the end of the test; (b) Specimen FR1-Fire-P2 after the fire test

The fire resistance test of specimen FR1-Fire-P2 terminated at 74 min because of the strength criteria failure; that is the specimen did not have sufficient strength to carry the applied load.

This fire endurance reveals the satisfactory performance of the fire protective coating as compared to that of specimen FR1-Fire-P1. According to Figure 11b, at the end of the test, the fire resistant coating in specimen FR1-Fire-P2 suffered many cracks; however, because of the presence of the keying mesh and its low thickness, any spalling of it did not occur. During the fire test of specimen FR1-Fire-P2, first, the debonding of the CFRP in the fire-exposed zone happened and the continuous carbon fibers transferred the load to the end anchorage zones. After the anchorage zones failure, the strength of the specimen decreased suddenly and subsequently, the slab collapsed.

At the end, the test results of all the tested specimens are summarized in Table 4.

Table 4: Fire endurance rating of experimental slabs based on strength criteria failure

Row	Slab designation	Slab properties			Fire resistance period (min)
		Width of CFRP strips (cm)	Thickness of Fire protection layer (cm)	Applied load (kN)	
1	CS-Fire	—	—	9.5	79
2	FR1-Fire	30	—	33	11
3	FR1-Fire-P1	30	2.6	33	47
4	FR1-Fire-P2	30	1.6	33	74
5	FR2-Fire	15	—	24	22

4. Conclusions

Based on this experimental research, the following conclusions can be drawn:

1. It was proved that the CFRP reinforcement is capable to increase the flexural strength of concrete slabs significantly. For the specimens tested in this experimental program, this increase in the load bearing capacity of the slabs was between 228% and 247%. However, the stress-strain curve of the CFRP up to the rupture is linear. As a result, the overall ductility and failure deformation of concrete slabs are reduced by the presence of the CFRP.

2. Strengthening a reinforced concrete slab with CFRP will increase the slab load carrying capacity and so, the applied service load to the slab can be increased. On the other hand, the CFRP is very vulnerable to high temperatures that the mechanical properties of its epoxy resin degrade at temperatures close to and above its glass transition temperature (usually is below 100 °C) which leads to the separation of the continuous carbon fibers. Because of these two factors, the fire resistance rating of a CFRP-strengthened reinforced concrete slab is much lower than that of the corresponding reference reinforced concrete slab. In this study, the fire endurance of the reference reinforced concrete slab was 79 min that reduced to 11 and 22 min for the strengthened slabs with different amounts of the CFRP. This issue reveals the intense need of fire insulation systems to protect the CFRP used in gravity retrofitting of reinforced concrete slabs.

3. The fire protection of the CFRP-strengthened reinforced concrete slabs with the gypsum-vermiculite material used in the study demonstrated that this type of materials is able to improve the fire resistance of the strengthened slabs significantly. In these experiments, a fire protection coating with 1.6 cm thickness could increase the fire endurance of the CFRP-strengthened

concrete slab from 11 min to 74 min. The reasonable thickness for the fire protection layer must be calculated to satisfy the mandatory fire resistance in accordance with building codes.

4. The installation method and details of a fire protection layer have a significant effect on its fire performance. In this study, in spite of an increase in the thickness of the spray-applied insulation from 1.6 to 2.6 cm, the fire endurance became lower contrary to our expectation. This result exhibits that for a large flat surface with a thick fire protection coating, a reinforcing mesh inside the fire protection coating is necessary to prevent it from detachment and maintain its integrity in high temperatures and large deformations.

5. In external strengthening of a reinforced concrete slab with CFRP strips, if a suitable external fire insulation or mechanical anchor can be provided at the ends of the CFRP strips, in a fire event, the continuous carbon fibers will separate from each other except the protected or strengthened ends. The bond of these fibers to the substrate at the ends will form a cable mechanism which will increase the slab strength and the slab fire endurance accordingly. This cable mechanism will fail at the time of the concrete cover detachment at the ends due to the high CFRP-induced tensile stresses.

Acknowledgement

Road, housing and urban development research center (BHRC) provided financial and laboratory supports for this research. The authors would like to appreciate Composite Sazeh Moghavem Company for supplying the needed FRP materials and their implementation. In this regard, the authors would also like to appreciate valuable cooperation of Dr. Sarafraz and staff of the fire department of BHRC; Mr. Koosha, Mr. Jamali Ashtiani, Mrs. Doroodiani, and Mrs. Askari moghadam.

Knowledge Gaps in the Construction Industry to Increase Societal Resilience: A Local and National Government Perspective

Chamindi Malalgoda, Dilanthi Amaratunga, Kaushal Keraminiyage and Richard Haigh

Global Disaster Resilience Centre, University of Huddersfield
Email: c.malalgoda@hud.ac.uk

Abstract

Over the last decade, a series of increasingly devastated natural disasters have been witnessed across the world. The disaster threats were further aggravated due to various social, economic and environmental trends, such as, growing population, urbanisation, inequality and global environmental change. This demanded a more proactive approach to reduce the vulnerability and exposure, and to increase resilience. For proper implementation of resilience measures, various efforts are required from construction practitioners. Accordingly, construction practitioners are expected to play a key role at each stage of the disaster management cycle. However, recent literature concerning disasters has highlighted the inadequate engagement of the construction industry in reducing the risk of disasters. This emphasises the need to engage the construction professionals adequately, in achieving a resilient built environment. Therefore, it is of paramount importance to provide construction industries with the necessary capacity and capability to plan, design, build and operate in such a way that will reduce vulnerability and exposure, and increase resilience. In order to address this challenge, CADRE (Collaborative Action towards Disaster Resilience Education), which is an EU funded research project, intends to develop an innovative professional doctoral programme that addresses the career needs, and upgrade the knowledge and skills, of practising professionals working to make communities more resilient to disasters. Accordingly, the first phase of the research involved, capturing the needs of 5 stakeholder groups associated in disaster resilience and management as well as current and emerging skills and ultimately knowledge gaps, applicable to construction practitioners towards enhancing societal resilience to disasters. In this context, the paper aims to analyse the current and emerging knowledge gaps of construction practitioners as highlighted by the national and local government stakeholders. Accordingly, the paper provides an extensive analysis of knowledge gaps, which were captured via 20 semi-structured interviews with national and local government stakeholders. Knowledge gaps were analysed in relation to social, technological, environmental, economic and institutional factors and property life-cycle stages. Some of the key knowledge gaps identified in the study are, business continuation management; damage assessments and claims; financing, budgeting and estimating; building codes, regulations and planning; resilient buildings and infrastructure; community empowerment; stakeholder management; legal frameworks and compliance; disaster risk assessment; environmental impact assessment and management; and knowledge management.

Keywords: resilience, national and local governments, knowledge gaps, construction, disasters

1. Introduction

There is a growing recognition that those responsible for the built environment have a vital role to play in developing societal resilience to disasters. If construction researchers and practitioners are to be able to contribute to reduce risks through resilient buildings, spaces and places, it is important that capacity is developed for modern design, planning, construction and maintenance that are inclusive, inter-disciplinary, and integrative. In order to address this challenge, EU funded research project, CADRE (Collaborative Action towards Disaster Resilience Education) will identify knowledge gaps, and develop an innovative professional doctoral programme (DProf) that integrates professional and academic knowledge in the construction industry to develop societal resilience to disasters. Through the development of an innovative and timely curricular and learning material, the project seeks to update the knowledge and skills of construction professionals in the industry.

Before developing the proposed DProf programme, it was important to identify the knowledge gaps in the construction industry to develop societal resilience to disasters. Accordingly, the paper aims to present the knowledge gaps that have emerged as part of this research. Capturing knowledge gaps involved, capturing the needs of various stakeholder groups associated in disaster resilience and management, as well as current and emerging skills, applicable to construction practitioners towards enhancing societal resilience to disasters. The primary and secondary data generated a long list of needs and skills. Finally, the identified needs and skills were combined ‘like-for-like’ to produce broader knowledge gaps. The paper provides an extensive analysis on the knowledge gaps identified through this process.

The paper begins with a literature synthesis on disaster resilience knowledge and skills. The paper then presents the analytical framework of the study. The scope of the paper is limited to findings gathered from one stakeholder group, national and local governments and therefore the paper investigates the role of the government in developing societal resilience to disasters. The paper continues with an analysis of the data gathered through semi-structured interviews based on five resilience dimensions, economic, environmental, institutional, social and technological and concludes with a list of key classifications derived from government stakeholders in enhancing the knowledge and skills of construction practitioners serving them to increase societal resilience to disasters.

2. Disaster resilience knowledge and skills

Hazards cause various disruptions to the built environment. The damage to the built environment accounts for most of the economic losses of disasters and its failure often determine the amount of fatalities (Witt et al., 2014). As such, professionals related to construction sector are expected to play a major role in mitigating such impacts of disasters. At the same time, it is the duty of the professionals attached to the construction sector, to plan, design, construct and operate necessary risk reduction infrastructure and other services to protect the communities exposed to hazards (Malalgoda et al, 2015). As such built environment should be planned, designed, built and operated in such a way that it can withstand at a time of a disaster. Therefore it is clear that the construction industry and the built environment professions play an important role in contributing to society's improved resilience (Haigh and Amaratunga, 2010). Max Lock Centre (2009) developed a guide to demonstrate the value of using construction professionals in disaster risk reduction and response. This guide shows how the relevant professional skills and expertise can be applied at all stages of disaster management. Some of the key activities highlighted in this guide are, risk and vulnerability assessment; disaster risk reduction (DRR) and mitigation; emergency water supply and sanitation; logistical planning; relief and transitional shelters; project planning and management; design, construction and monitoring; physical condition surveys and audits; compensation packages; resource mapping; housing need assessment; land survey and acquisitions; physical planning; infrastructure planning and implementation; property rights and claims; financial planning and management; and advice on regulations and codes. Especially, poor urban planning and poorly regulated building codes have aggravated exposure to hazards (Bosher, 2014; Malalgoda et al, 2014) and as such utilising construction practices, building codes and technology that can withstand the exposure is of paramount importance (Ireni-Saban, 2012). As such it is clear that construction practitioners have a key role in DRR and management and their professional skills and expertise need to be deployed in disaster risk reduction and management. In addition to these, Norman and Binka (2015) highlighted the importance of soft skills such as leadership in building disaster resilience and response. A study conducted in Sub-Saharan Africa revealed that leadership capacities need to be strengthened through continual professional developments and formal education in order to build resilience and to improve response. It is important to understand that the disaster resilience requires efforts of various stakeholders and would require a multi-sectoral and inter-disciplinary approach (Haigh and Amaratunga, 2010). As such collaborative actions are required for a better resilience outcome (Ireni-Saban, 2012), which highlights the importance of knowledge and skills, related to collaborative working and community interactions.

Indigenous knowledge is another important aspect when it comes to DRR and resilience. According to Ireni-Saban (2012) local knowledge places a greater importance, including understanding communities at risk, including their practices, traditions, customs and beliefs. By understanding the indigenous knowledge, such as local skills and materials and how it can be successfully used and its success in coping with disasters over time (UNISDR, 2008) would undoubtedly benefit in the preparation for future disasters. However, according to Gaillard and Mercer (2012) there is a gap in integrating local and scientific knowledge because of the lack of trust between stakeholders operating at different level. As a result, contributions of local communities are often disregarded which lead to gaps between policy development at the national level and the practice at the local level. This emphasises the need of multi stakeholder approach, inclusion and empowerment.

As discussed above, various knowledge and skills are required to better perform the tasks associated with risk reduction. As such, knowledge plays a major role in disaster risk reduction and resilience (Weichselgartner and Pigeon, 2015). As a result of prominent gaps in knowledge, Sendai Framework for Disaster Risk Reduction (2015-2030) has identified the need of enhancing the capacities of relevant stakeholders and industries. The Framework provides recommendations regarding the creation and dissemination of knowledge (Weichselgartner and Pigeon, 2015). Accordingly, the framework suggest to “build the knowledge of government officials at all levels, civil society, communities and volunteers, as well as the private sector, through sharing experiences, lessons learned, good practices and training and education on disaster risk reduction, including the use of existing training and education mechanisms and peer learning” (UNISDR, 2015). Professionals attached to construction sector play an important role in disaster resilience and management. As such, construction professionals require continuous update of knowledge and education in order to effectively contribute to disaster management (Thayaparan et al, 2014). It is therefore important to design educational and training courses to enable them to successfully fulfil this role (Witt et al., 2014). Therefore as argued by Bosher et al. (2007), risk and hazard awareness training needs to be integrated systematically into the professional training of architects, planners, engineers, developers, etc. The next section presents the analytical framework and methodology of the study.

3. Analytical Framework and methodology

The initial framework of the study is a three dimensional framework consisting of the following parameters:

Built environment stakeholders: National and local government organisations; Community; NGOs, INGOs and other international agencies; Academia and research organisations; and Private sector.

Dimensions of resilience: Economic Resilience; Environmental Resilience; Institutional Resilience; Social Resilience and Technological Resilience

Stages of property lifecycle: Preparation Stage (PS); Design Stage (DS); Pre-Construction Stage (PCS); Construction Stage (CS) and Use Stage (US)

The framework was developed through an extensive consultation process with project partners and was refined throughout the first year of the project with the emerging literature findings and the opinion of stakeholders who has been interviewed to capture the labour market demands in construction industry to increase societal resilience to disasters.

The research discussed in this paper is focussed on analysing the market demands of one of the stakeholders, national and local governments. Accordingly, the paper analyses the semi-structured interviews conducted with national and local government organisations. Semi-structured interviews were conducted with a total of twenty respondents from the “national and local government” stakeholder group across different countries and continents. The respondents identified and interviewed in this category were individuals that were attached to national and local government institutions, involved in various activities related to disaster resilience and management. The interviews were aimed at capturing the needs as well as skills, applicable to construction professionals towards enhancing societal resilience to disasters. During the interviews, special interest and focus was given on the needs of national and local government organisations engaged in disaster resilience and management and the skills required from construction industry professionals serving them. Accordingly, the interviews were more of a discourse structured around the stages of disaster management cycle. The analysis was done using NVivo (version 10). The themes were presented under two main headings i.e. Needs and Skills. The category "Needs" covers the stakeholder requirements that emerged from the interviews as well as the demands specifically made by interviewees. Also, what the interviewees believe should be in place while professionals relate with them to enhance societal resilience were categorized under the heading "Needs" in the analysis. During the interviews, some set of skills were emerged; some were displayed by professionals while serving to reduce the threats posed by natural and human induced hazards and some that are desired by interviewees. These set of skills were categorized under the heading "Skills". All needs as well as skills were categorized into five dimensions of resilience (Social, Economic, Institutional, Environmental, Technological) and each of the dimensions of resilience is sub-headed with the five stages of property lifecycle, Preparation, Design, Pre-construction, Construction and Use stage. The interviews generated a long list of needs and skills with respect to the property lifecycle stages under the respective dimensions of resilience. Finally, the identified needs and skills were combined 'like-for-like' to produce broader level of knowledge gaps (themes).

3.1 Government as a stakeholder

A number of parties are involved in the process of increasing societal resilience to disasters, including community and citizens' groups, local governments, the private/corporate sector, the national government, civil society organisations, external actors, professional groups and the media. There should be adequate coordination among the interested parties in order to overcome the challenges posed by a disaster, successfully. Between these stakeholders, a government of a country plays a predominant role. All activities related to disaster management are usually centred at governmental level, and hence, governments can be identified as the principal stakeholder in disaster management (Moe and Pathranarakul, 2006). Usually the government assigns the responsibility for each task to different ministries or may form new authorities or committees and assign the responsibility for different tasks to these authorities or committees (Wolensky and Wolensky, 1991). To be successful, proper partnerships and cooperation are essential between local and national governments and civil society in order to reduce the costs of risk reduction, ensure local acceptance and build social capital (UN-ISDR, 2010). Recent literature highlight administrative shortcomings that prevent affected communities recovering from disasters (Ireni-Saban, 2012). In overcoming these challenges, government require professional services from the construction professionals to prevent, mitigate, prepare and recover from disasters. According to Bosher (2014) number of structural and operational obstacles does exist in making the built environment resilient to disasters and lack of knowledge and skills were key among others especially in developing country context (Malalgoda et al, 2014). Thus, it is very important to identify the knowledge gaps and develop educational programmes to cater the identified knowledge gaps. The next section analyses the data gathered through semi-structured interviews.

4. Data analysis and discussion

4.1 Economic Resilience

According to Seneviratne et al (2010) economic factors are two-fold, economic planning measures and financial measures. Aspects relating to production, distribution and consumption of goods and services are considered as economic planning measures and aspects relating to money and management of monitory assets are considered under financial measures. In terms of economic resilience, most of the interviewees identified the gaps in business continuity management. Some of the key highlights within this theme were business continuation strategies and business continuation plans. Having a business continuation strategy/plan is of paramount importance in order to make sure that business is up and running after a disaster. Local authorities have a responsibility to promote business continuity to businesses and the interviewees considered this as a key knowledge area within the domain of disaster resilience. Financing, budgeting and estimating was another key theme identified under economic resilience. This covers number of sub-themes such as, sourcing of funds, investment appraisals, construction budgets, cost control, contingency management, financial management relation to disaster resilience and, transparency and accountability. Damage assessments and claims is another important theme highlighted by the interviewees. Under this theme, interviewees highlighted the importance of knowledge and skills related to, property insurance, damage assessments, valuation, and compensation for damages. This include, assessing what damage has the disaster caused and what works need to be done to get back to pre-disaster condition and what further work could be done to prevent or reduce the risk of happening it again. Process and quality management was also categorised under economic resilience as it highlighted the importance of resource management and prioritising work. In particular, prioritisation of work is very much relevant in the context of disaster resilience due to the restricted budgets. Thus, identifying the most critical activities and prioritising projects is very important in implementing DRR projects. Resource management and prioritisation also has a link to the next theme, which is social and cultural awareness. Interviewees highlighted the importance of the use of local knowledge, skills and materials and emphasised the necessity of deploying economically feasible and socially acceptable solutions that would enhance societal resilience to disasters. Another theme was the contracts and procurement. Interviewees argued the importance of knowledge and skills with regard to different procurement strategies which facilitate rapid restoration; different forms of contracts such as nec3 option G which allows instructing task orders during incidents; framework contracts for incident management works; and rapid response of supply chain. All these are formed under the theme, contracts and procurement. Table 1 highlights all themes derived in relation to economic resilience and their relevance to different stages of property life cycle.

4.2 Environmental Resilience

Factors relating to environment, ecology and sustainability were considered under environmental resilience. Similarly, analysis of semi-structured interviews facilitated deriving number of themes for environmental resilience. Each of these themes was derived from various needs and skills identified by the interviewees. One of the key themes identified under this category was the risk and need assessment. This theme was identified as a result of sub themes such as, preventive structures, identifying vulnerable population and properties, hazard and risk mapping, identifying suitable places for relocation and, forecasting and warning. In doing so, it is very important that community know that they are at risk, so that they will be more engaged and will be willing to take action. For an instance, they can equip with property level protection, for an example, in the case of floods, they can install floodgates for their doors and windows and flaps for inlets and vents into their houses. The theme, knowledge management arise based on interviewees arguments on the need for, access to related data and information and access to required software and technology such as GIS. Lack of data and information is a prevailing issue especially for more remote areas. These include, lack of hazard and risk maps, water tables, soil types, rainfall data, geological data etc. Under environmental management, interviewees highlighted the need of understanding and managing the environmental impacts, which trigger disasters, forecasting, early warning, weather and climate change, use of resilient designs, materials and construction techniques, environmental impact assessments and local topography. Materials and resource management also plays a role in environmental resilience. Accordingly, interviewees highlighted the importance of having the knowledge of resilient and environmentally friendly materials and other resources in order to enhance the environmental resilience. For an example, one interviewee highlighted the importance of selecting materials to match the location, climate, and soil types while another highlighted the importance of resource management to reduce the wastage. Sustainability and resilience is yet another important theme identified under environmental resilience. It covers number of sub themes such as, sustainable design solutions, selection and use of sustainable materials and technologies and ensuring sustainability of resilient solutions. Table 2 highlights all themes derived in relation to environmental resilience and their relevance to different stages of property life cycle.

4.3 Institutional resilience

Institutional resilience, as defined in this paper refers to the political, legal and institutional factors. Aspects relating to government and policies are considered as political factors; aspects relating to law, accepted rules and regulations in managing disasters are considered under legal factors; aspects relating to an organisation linked to disaster management are considered under institutional factors (Seneviratne et al, 2010). As shown in Table 3, various themes were identified in relation to enhancing institutional resilience. One of the key themes identified was stakeholder management. Stakeholder management was derived from a combination of responses given by the interviewees. Some of these include, multi stakeholder engagement, appropriate institutional arrangements, clear definitions of roles and responsibilities, coordination between different organisations, collaborative working, relationship with other stakeholders and communities, commitment to disaster management and resilience. This theme further incorporated the interviewees' responses such as communication skills, team working and management and leadership skills. Legal frameworks and compliance is another key theme under institutional resilience. This theme incorporated sub themes such as, policies, plans and legal frameworks for disaster resilience, disaster risk reduction strategies, knowledge on prevailing laws and implementation of laws and regulations. Leadership and people management has been identified as a separate theme as it was a concern for most of the respondents. However, this has a close link to the theme, stakeholder management, and include, sub themes such as multi stakeholder engagement, understanding community needs, engaging communities, collaborative working, conflict management, leadership skills, people management skills, commitment for disaster risk reduction and proactive thinking. Governance is yet another important theme classified under institutional resilience. The theme was derived from number of sub themes, such as, institutional arrangements for disaster resilience;

commitment to disaster risk reduction; coordination between stakeholders; and policies, plans and legal frameworks for disaster resilience.

4.4 Social resilience

Social resilience was defined based on Cacioppo et al (2011) definition for social resilience, which is revealed by capacities of individuals, or groups, to foster, engage in, and sustain positive social relationships and to endure and recover from disasters. Similar to previously identified resilience dimensions, number of themes was also derived under social resilience dimension. Community empowerment is the most noted theme under social resilience. In terms of community empowerment, interviewees highlighted the importance of community engagement and participation, maintaining or re-establishment of community relationships, working with the community, understanding community needs, empowering community and social cohesion. Especially in multi-cultural societies, communities aren’t always engaged or integrated, however after an incident community relationship grow stronger and participate more willingly. Team working is also an important theme identified under social dimension which includes, collaborative working, working with the community, understanding community needs, effective involvement of the community and team working. Communication was classified as a separate theme due to the importance placed by the interviewees on communication. Communication skills are especially required when dealing with disaster-affected communities, to understand their emotional and psychological conditions and to avoid any further harm. Sometimes it is difficult to convince the vulnerable population to take preventive action due to cost, time and other constraints. As such, good communication skills are of paramount importance to ensure that they understand the risk and act upon to reduce it. Another important theme derived under social dimension is the social and cultural awareness. This incorporated interviewees' responses such as the importance of the use of local knowledge and skills, use of local businesses for repairs and reconstructions, and selection of approaches suitable to local context. Table 4 highlights all themes derived in relation to social resilience and their relevance to different stages of property life cycle.

24	*Time management*	*x*	*x*	*x*	*x*	

4.5 Technological resilience

The final dimension of resilience was about technological resilience. This includes "application of scientific advances including any tool, technique, product, process and method to benefit disaster management" (Seneviratne et al, 2010). In terms of technological resilience, number of themes was identified and this section highlights the key themes identified under this dimension of resilience. The first theme identified was building codes, regulations and planning. This was derived from the sub themes, awareness of property related regulations and policy, knowledge of construction codes for different properties, knowledge on planning and building regulations and knowledge of planning permissions. In supporting this, one of the interviewees stated, “one of the things that put people and businesses at more risk than anything is permitted developments within flood plains and close to rivers”. Land next to rivers and next to water causes or flood plains are relatively cheaper, however, it is important to influence planners and decision makers to not to allow any developments within flood plains. The next theme identified under this was the resilient buildings and infrastructure. This theme covered a variety of sub themes such as, resilience planning, designing and construction, advice and guidance on design and construction of resilient structures, monitoring and supervising the construction and operation of resilient structures, use of resilient construction processes and techniques, development of resilient transport networks, identifying vulnerable population and properties, understanding impacts of disasters on the built environment, addressing disaster resilience in preparation and design stages, proactive approaches to disaster risk reduction or pre-disaster management, build back better and development of preventive structures and methods. There are so much that can be done to prevent or mitigate disasters, for an example, to manage flood risk, some of the things that can be done are, flood walls, embankments, storage areas and flood gates and vent protection to protect individual properties. Project and construction management is a combination of sub themes such as knowledge and experience of construction technology, knowledge of construction codes for different properties, resource management and monitoring and supervising the construction and operation of resilient structures. Table 5 highlights all themes derived in relation to technological resilience and their relevance to different stages of property life cycle.

5. Conclusions

A number of needs and skills were identified in respect to various resilience factors and property life-cycle stages. Finally, labour market needs and skills with respect to resilience dimensions across property life stages were filtered to generate a total list of 33 knowledge gaps. 13 (out of 33) gaps emanated from labour market needs and skills under economic resilience with their respective property lifecycle stage. 14 (out of 33) gaps originated from labour market needs and skills under environmental resilience. 22 (out of 33) gaps emanated under institutional resilience. 24 (out of 33) gaps derived under social resilience, and 13 (out of 33) gaps produced under technological resilience. It is evident that more gaps were derived from social resilience, followed by institutional resilience. The paper analysed the knowledge gaps in the construction industry to develop societal resilience to disasters from the perspective of national and local government stakeholders. The paper was based on an EU funded project, CADRE (Collaborative Action towards Disaster Resilience Education) and as part of the project similar studies were conducted to obtain the views of other stakeholders, such as community, private sector, academia and non governmental organisations. Finding of all stakeholders were collated to derive a comprehensive list of knowledge gaps and at the next phase of the research it is expected to validate these findings through stakeholder seminars. Finally, it is intend to develop a professional doctorate to cater the identified knowledge gaps.

6. Acknowledgements

Abstract

Climate change continues to pose major challenges to those responsible for the management of built assets. Whilst mitigation is largely being driven by legislation and corporate social responsibility, adaptation has to compete alongside general built asset management needs. As such, adaptations to address longer-term building performance issues (such as those posed by climate change) rarely get prioritised above more immediate, short-term needs. However, failure to adapt a built asset to climate change could result in significant premature obsolescence if work is not programmed in a timely fashion. This paper will present the results of a case study of climate change adaptation of UK social housing.

The project reports the results of an in-depth participatory action research project with a London based social landlord to develop and test a 6 stage climate change adaptation framework and risk based model as part of its built asset management strategy. The project developed metrics to analyse the performance of the housing stock against climate change scenarios for current time and 2050. The project also examined the potential (options appraisals and cost/benefit analyses) for a range of adaptation solutions to close the performance gap and developed performance thresholds to prioritise adaptations into long term built asset management plans. These plans were developed against a range of futures scenarios through interviews and workshops with senior decision making stakeholders within the social landlord's organisation. This paper will present the practical results from this study along with a new theoretical model that integrates resilience theory, risk framing and performance management into built asset management (maintenance and refurbishment) planning. The paper will conclude with a 10 step asset management framework that was developed as an aide memoir to guide other social landlords through the climate change adaptation planning process.

Keywords: Adaptation, Built Asset Management, Housing, Risk, Resilience.

1. Introduction

The world’s climate is changing in ways that will have a significant impact on both human society and the built environment (IPCC, 2014a). These changes affect not only average temperature but also results in changed temperature patterns and in particular the severity and frequency of extreme weather events (ibid). Whilst the impact of climate change is different across the world it is urban centres that are likely to be at greatest risk and where action needs to be taken to improve resilience to climate change threats (IPCC, 2014b). To this end actions that accelerate adaptation of the built environment are required (ibid). In particular actions are needed that reduce the vulnerability and improve the resilience of urban systems (e.g. housing, buildings and infrastructure etc.) and provide the governance, policies and incentives to realise adaptive capacity (ibid). This paper reports the development of a built asset climate change adaptation model for social housing in London. The paper supplements a previous publication by Jones et al (2013) where the climate risks to London were discussed and the theoretical base to the risk framework model was presented. This paper provides details of a participatory action research project that integrated the risk framework model with built asset management theory and tested the resulting model against approximately 4000 housing units in London. The paper concludes with a 10 step approach to adaptation planning that should allow Facilities Manager’s to develop built asset management plans to reduce the vulnerability and improve the resilience of their built assets.

2. Background

Whilst in the UK the impact of a changing climate on new buildings can be accommodated through new design standards and planning guidance (CLG, 2007; CLG, 2009; Environment Agency, 2009), the same instruments are not universally applied to existing buildings. As such many existing buildings could be vulnerable to the impacts of climate change, and particularly extreme weather events (EWEs), requiring adaptation if they are to remain viable (Saunders & Phillipson, 2003). Further, in the UK adaptation to climate change is not generally considered part of routine maintenance/refurbishment and it is unclear whether the approaches used by the climate change community (UK climate projections, risk frameworks) can be effectively integrated into built asset management models. These issues are particularly acute in London where it is already apparent that the changing climate could have a significant impact on the ability of existing social housing to provide the quality environment expected by residents (Jones et al, 2013). This poses a problem for many landlords; how do they prioritise adaptation for an uncertain future climate over solutions that improve the immediate quality of their housing stock today?

The EPSRC Community Resilience to Extreme Weather (CREW) project studied the potential impact that a range of extreme weather events could have on the vulnerability, resilience and adaptive capacity of buildings in the SE London Resilience zone (Hallet, 2013). The CREW project used the UKCP09 probabilistic weather files to predict weather patterns across SE London and then superimposed these onto topographical and drainage information to generate extreme weather impact scenarios for 2020 and 2050. The scenarios were then used to investigate the risks to housing of overheating and flooding and to identify adaptation solutions that could reduce vulnerability and improve resilience. One of the key outputs from the CREW project was a risk based adaptation framework (Fig. 1) that sought to guide facilities managers through the climate change adaptation assessment process. In this framework future scenarios are used to predict the degree of change over current conditions that could occur to a building(s) as a consequence of climate change. For each potential impact a risk assessment is then performed to identify impacts and cost adaptations. These adaptations are then prioritised and integrated into contingency plans (Jones et al, 2013). The application of the adaptation framework forms the background to this project.

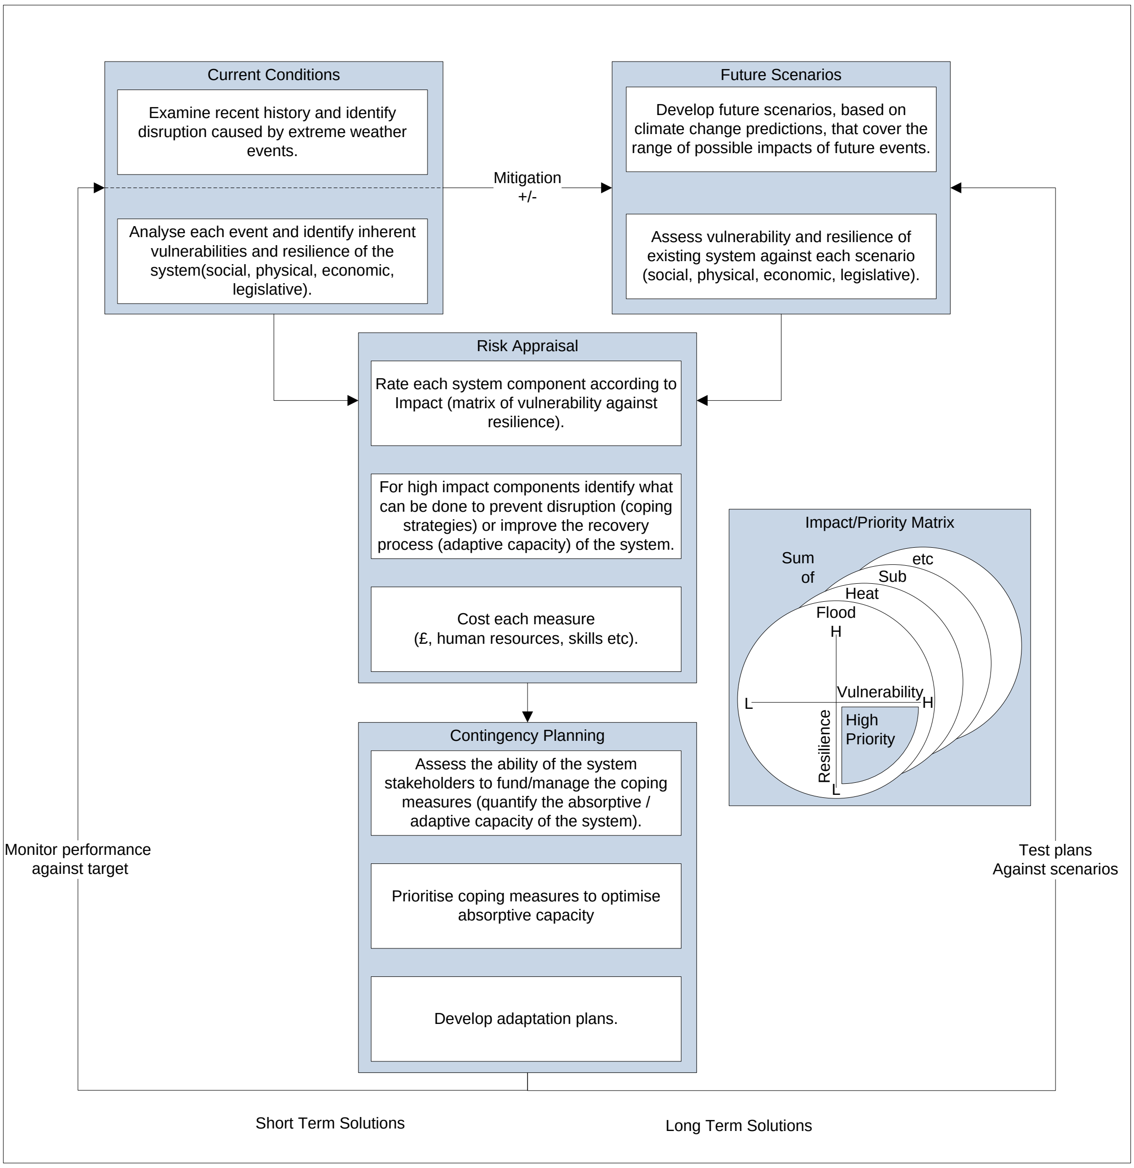

Figure 1: Adaptation Framework (Hallett, 2013)

In order to test the applicability of the adaptation framework to inform maintenance and refurbishment plans it needs to be integrated into a performance based built asset management model (Jones and Sharp, 2007) (Fig. 2). The performance model involves: identifying the critical success factors (CSF's) against which maintenance and refurbishment (including climate change adaptation) will be judged; establishing a series of performance toolkits that measure the performance-in-use of each property; establishing the underlying cause of any underperformance; developing action statements that describe the required improvements in performance; developing and evaluating adaptation solutions against the organisations CSF's; and evaluating the success of the adaptations and provide feedback to the organisation's climate change adaptation policy and strategies. This project developed the tools necessary to achieve this integration. This paper builds on work previously published (Jones et al, 2013) where the background to, and further details of, the factors that affect the vulnerability, resilience and adaptive capacity of UK social housing to climate change can be found.

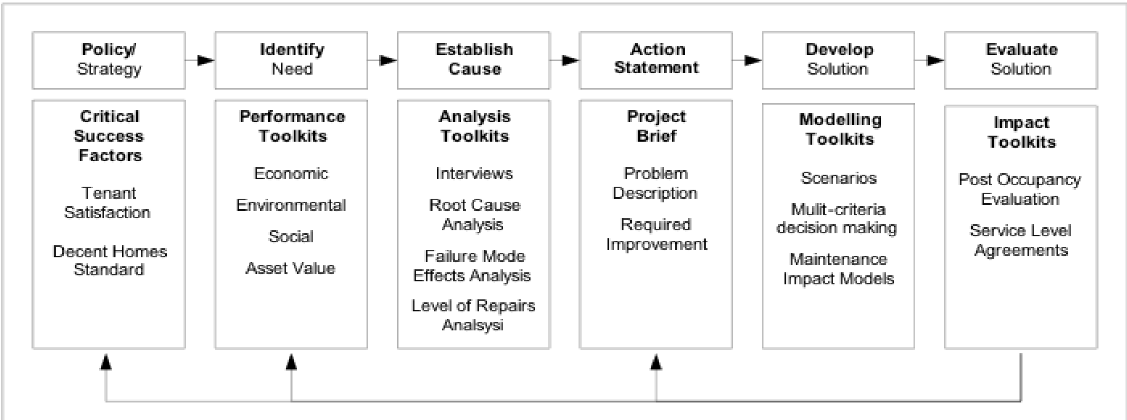

Figure 2: Performance Based Built Asset Management Model (Jones and Sharp, 2007)

3. Methodology

The focus of the project was a UK Registered Social Landlord (RSL) that owns and manages approximately 4000 homes, located mainly in inner London. The RSLs property portfolio was extremely diverse, ranging from large modern purpose built blocks, to Victorian street properties. Whilst he RSL owned few whole houses, more than 86% of its stock was made up of maisonettes and flats (the majority the result of the conversion of houses rather than purpose built blocks). Forty six percent of the stock were bedsits or one bedroom properties, 33% were two bedroom properties; 18% were three bedroom properties; and the remaining 3% were 4 and 5 bedroom properties. Forty nine percent of the stock was built before 1919; 8% between 1919 and 1944; 22% between 1945 and 1980; and 21% post 1980. A number of the RSLs properties were Listed Buildings and others were in Conservation Areas. At the time of the project the majority of the stock was in a reasonable state of repair, with the RSL spending approximately £11m per year on maintenance/refurbishment and a further £25m on new build. The RSL had a comprehensive asset management database, including an up to date condition survey of their stock, and had maintenance/refurbishment plans in place for general improvements over a 5, 10 and 30 year period. The RSL also had detailed contingency plans to deal with flooding events. For logistical reasons the fieldwork was limited to a sample of the RSL's housing, of 1255 properties or 31.46% of their total stock, located in a single London Borough.

A series of facilitated workshops, semi-structured interviews, building surveys of archetype housing units (undertaken by the RSLs consultants using standard UK guidelines), building simulation models and life cycle costing analyses were used to develop and test a range of practical adaptation planning tools that could be used to integrate climate change adaptation into the built asset management process. The field work for this project took place in 2012/13. Although the project examined both flooding and overheating for the sake of brevity only the flooding results are presented here.

4. Results

The following section describes the process that the participatory action research team went through to integrate the adaptation framework (Fig 1) into the performance based built asset management model (Fig 2).

Step 1 - Identify Policy/Strategy Drivers: The first task was to establish the Critical Success Factors (CSFs) against which current and future performance would be judged. This was done through discussion with senior managers and by reference to the RSLs strategic plan and operational documents. The RSLs approach to the quality of their housing was governed by their 'Performance Standard' that described expectations for the quality of the stock. Although the Standard didn't explicitly address the impact that climate change could have on a house it did establish the general principle that:

> *"Your home should be in good working order and fit for purpose - it should meet a certain set of standards, both inside and outside and in shared and private areas to make it a safe and healthy environment to live in."*

The Standard also implied that the RSL would adopt a proactive approach to ensuring that its homes meet the Standard. To this end the 'Standard' provided the basis from which CSF's were derived and against which the success of adaptation solutions would be measured. For flooding these were:

1) Reduce disruption to tenants from flooding events. Performance thresholds to relate to the degree of disruption that a flood event would cause to tenants.
2) To continue to maintain tenant confidence and trust in the RSLs ability to deal with climate change issues. Performance thresholds to be measured through the tenant satisfaction survey.

Once the CSFs had been established a set of performance toolkits were developed to help identify adaptation needs.

Step 2 - Identify Need: Toolkit 1 sought to identify those properties that were located in a potential (current and future) flood zone AND were vulnerable to water ingress. This toolkit involved superimposing the RSLs properties onto flood maps using geo-referenced data and a geographical information system to identify those properties that were at potential risk of flooding. Each property was then examined in more detail (using the RSLs asset management database, Google Street View, and external street surveys) to identify the potential for water ingress assuming a 0.5

m flood in the street immediately adjacent to the property. A combination of the potential flood risk and likelihood of water ingress into the property was used to determine the property's level of vulnerability (Fig. 3)

Toolkit 2 sought to quantify the impact that exposure to a flood would have on the performance-in-use of those properties at risk of such an event. Assessments of the potential impact of flooding events on a sample of those properties identified as highly vulnerable to such an event was used to identify their coping capacity. A combination of the potential damage that a flood event would cause and the recovery time it would take to return the property to its pre-flood performance level was used to categorise the properties coping capacity threshold as Low Medium or High.

		Likelihood of a flood event			
		No likelihood	Low	Medium	High
Likelihood of water ingress to the property / damage to critical infrastructure	No likelihood	Not vulnerable	Not vulnerable	Not vulnerable	Not vulnerable
	Low	Not vulnerable	Low	Low	Low
	Medium	Not vulnerable	Low	Medium	Medium
	High	Not vulnerable	Low	Medium	High

Figure 3: Typical vulnerability threshold matrix for flooding

The vulnerability and coping capacity for each property identified as 'at risk' of flooding was plotted onto a Resilience Matrix (Fig. 4). From this figure a number of properties were identified as highly vulnerable with a low coping capacity and these would be prioritized for early action in the asset management plan. Those properties that were highly vulnerable but had a Medium/Low coping capacity would be prioritized as short-medium term action in the asset management plan. Those properties that had a low vulnerability and high coping capacity would be reviewed at regular intervals as more climate change data became available.

Step 3 - Establish Cause: Internal surveys of 26 typical properties were undertaken to establish the root cause of flooding damage and to identify potential adaptation solutions. In all cases these solutions were affected by legacy design decisions made when the buildings were newly constructed or underwent major refurbishments.

Adaptation options in the form of resistance (preventing water entering the property) and resilience (increasing speed of recovery once the property has flooded) measures were considered for each surveyed property. From the surveys it was clear that it would be very difficult (if not impossible) to prevent water entering basement flats or basement floors of individual houses. Further, once water had entered the property it was likely to cause significant damage to both building components and fixtures & fittings that would require significant work in order to return the property to a habitable condition. Thus the best adaptation strategy for this type of property would be to let it flood but to improve the resilience of building components (non-structural) and fixtures & fittings to shorten the time it would take to return the property to a habitable condition. Similar analyses were undertaken for ground floor flats, houses and communal areas and a set adaptation principles (Fig 5) were developed in the form of an ***Action Statement (Step 4)***.

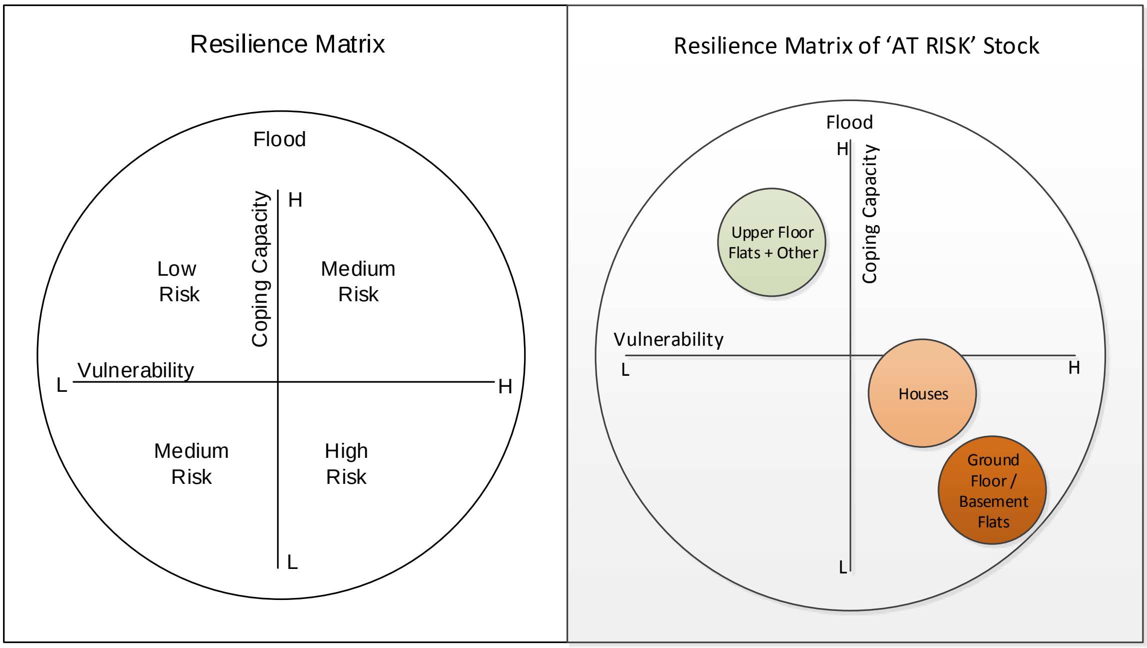

Figure 4: Generic resilience matrix and specific resilience matrix for flood risk properties

Adaptation Guiding Principles

- If it is economically feasible to prevent flood water entering a property then this should be adopted.
- Water resilient components, fixtures and fittings should be installed when flood ingress is likely.
- Ensure all essential services are resistant to a flooding event.
- Work with residents to prepare personal flood action plans.

Figure 5: Adaptation principles

Step 5- Develop Solutions: The potential (technical and cost/benefit) for a wide range of flood resistance and resilience measures were assessed for each archetype property. A set of triggers and thresholds were developed to allow potential adaptations to be prioritised for inclusion into the built asset management plan. At the strategic level these triggers and thresholds tended to be statements of intent or desire, rather than quantified metrics to instigate an action. These statements of intent were related directly to the RSLs 'Performance Standard' and were expressed as commitments for each quadrant of the Impact/Priority Matrix shown in Fig. 4 and summarized in Table 1.

In addition to the generic triggers and thresholds outlined above, specific action should be taken in Year 1 of the adaptation plan to address known, current problems. Where the problems are known, but the scale is unknown, action should be taken in the first 5 years of the adaptation plan to quantify the scale of the problem. Where there is uncertainty about the potential problem or a solution the situation should be regularly monitored. These thresholds and triggers are summarized in Table 2.

Table 1: Action trigger/thresholds for flooding adaptations

Resilience Quadrant	Action Trigger/Threshold
High Vulnerability / Low Coping Capacity	Take action to improve resistance and/or resilience in the next 5 years.
High Vulnerability / High Coping Capacity	Take action to improve resistance and/or resilience in years 6 to 10.
Low Vulnerability / Low Coping Capacity	Take action to improve resistance and/or resilience in years 11 to 30.
Low Vulnerability / High Coping Capacity	Take no action.

Step 7 - Adaptation Strategy: Once all the previous described steps had been completed an adaptation strategy was developed to address the potential impact of flooding both today, and in the future. A typical part of the adaptation plan is shown in Table 3.

Table 2: Thresholds and triggers for action in an adaptation plan.

Year to Action	*Threshold*	*Trigger*
1	Know scale of problem and solution	Known level of risk is high
2-5	Know problem exists but don't know scale or	Establish level of risk
6-30	Unsure if problem exists. Don't have a solution	Continue to monitor risk

Table 3: Example extracted from the adaptation strategy

Property Type	Vulnerability - FLOODING	Timescale for Action
Vulnerable Street Houses	Where ever possible floodwater should be prevented from entering the house. Depending on the depth of any water entering the house (will depend on floor level above the street, existence of a basement etc.) resilient fixtures and fittings should be used to ensure that the house can be returned to a habitable condition in the shortest period of time.	
	Undertake detailed surveys of the vulnerable properties identified in this report to identify the flood resistant actions required to prevent water entering the property (including the sealing of air bricks, appropriateness of door dams, non-return valves on drainage and foul water systems etc.). Identify the impact that any floodwater entering the property would have on the post-flood recovery period. These plans should include a detailed assessment of post-flood	Year 2-5

	building works and an estimate of the time to return the house to a habitable (or part habitable) condition.	
	Assess the potential of resilience measures to reduce the estimated time to return the house to a habitable (or part habitable) condition. In particular examine measures that improve the resilience of essential services, kitchen and bathroom areas. Undertake a more detailed cost/benefit analysis of these measures and implement those that are appropriate when next refurbishment is planned.	Year 2-5
	Ensure that the RSL is signed up to the environment agency early warning service and develop a communications strategy that informs its residents of an impending flood events and keeps them informed of progress through the clean-up and repair phase.	Year 1
	Engage with the residents living in these houses to ensure that they are as prepared as possible for potential flooding events. Consider providing labour to assist residents in the removal of personal and treasured items to the upper floors of the houses.	Year 1
	Ensure that arrangements are in place with alternative landlords to provide temporary accommodation for those residents displaced by a flood.	Year 1

5. Discussion

This project sought to test the theoretical adaption framework developed through the CREW project by developing a set of tools that could be used to integrate it into a performance based built asset management planning model. Through this process a new 10 step model for adaption planning for future climate change was developed. This model is summarised in Table 4.

Table 4: Ten step adaptation planning model

Step		**Actions**
1	Identify current climate related threats to your stock	Examine local histories for details of climate related impacts. This could involve reviewing national and local climate risk assessments (e.g. flood maps) and identifying previous extreme weather events that have affected the region where properties are based.
2	Develop future climate impacts scenarios that are relevant to your circumstances	Identify future climate impact change predictions for your area. This could include reviewing national climate change assessments where they exist and undertaking absolute climate change assessments where possible. In most cases individual organisations will not have access to the resources necessary to undertake absolute assessments so relative (step-up or morphing) assessments can be used as an alternative to predict the scale of potential future extreme weather events.

3	Map current and future climate threats to your property portfolio	Examine known vulnerabilities of your stock to the key weather impacts. This would include geo-mapping the location of each of your properties onto current and future climate change risk maps (e.g. flooding, overheating etc.) and identify the numbers of properties at risk and the level of the risk (e.g. flood type, flood depth, flood duration etc.) for each property. Review the ability of existing disaster planning to cope with any increased incidence of extreme weather events.
4	Identify the coping capacity of your properties to current and future climate threats	Assess the impact that a climate related event would have on your property portfolio. This would involve identifying typical property archetypes for a range of climate change events (flood impact assessments, overheating etc.) ensuring that the organisation have the data (either in their asset management system or through housing surveys) to assess the vulnerability and coping capacity of the property to each event. Develop organisation specific vulnerability and coping capacity thresholds for each property archetype against each climate change impact. Plot vulnerability and coping capacity onto a Resilience Matrix.
5	Identify possible adaptation solutions	Identify appropriate resistant and resilience measures. This will include modelling the effect of a range of adaptation options against each archetype for each climate change impact and assessing the technical feasibility of retrofitting adaptation measures.
6	Articulate required improvements to the performance of your properties	Identify performance expectations for your properties against each climate change impact. For example, • Let properties flood and ensure rapid recovery; or • Prevent water ingress where ever possible; or • Ensure at least one room in every property does not over heat; etc.
7	Identify priorities	Develop priority thresholds based on the performance expectations identified in step 6. Identify what types of adaptation should occur in years 1-5; 6-10; and years 11-30?
8	Develop adaptation strategy	Identify the actions to be taken for each vulnerable property archetype. This could include identifying known problems for immediate action in year 1; gathering missing data (surveys) for high risk properties in years 1-5; and monitor performance of medium risk properties in years 6-30. All other missing data should be collected as a part of the normal re-survey cycle.
9	Prepare adaptation plan	Identify individual properties requiring action in years 1-5 (steps 3, 4 and 8). This will involve detailed (property level) assessments of the potential for different adaptation solutions identified in step 5 to achieve the performance improvements identified in step 6. Use priority thresholds (step 7) to order adaptation actions. Cost each solution and select appropriate ones for inclusion in the adaptation plan. Develop an adaptation programme for the works over a 5 year period.

10	Implement and test plan	Monitor effectiveness of interventions and close the feedback loop. If you experience a climate related event how well did your plans work? If you don't experience an event then test your plans against a simulation. Review the effectiveness of your Disaster Management and Contingency Plans

Whilst the theories supporting the adaptation framework and the performance based built asset management complemented each other, and at the theoretical level integration was fairly easy to achieve, a number of issues were identified that limited its practical application.

Whist access to public data on past extreme weather events and potential impact of none climate change future events was generally available and suitable to inform step 1 of the adaptation planning model the data required for steps 2 and 3 wasn't. Whilst UKCP09 climate change projections provided a means of generating future weather patterns the lack of future risk assessments (e.g. future flood risk maps, local heat islands etc.) made it difficult to assess the future vulnerability and resilience of the housing stock. As such the project scenarios were based on possible relative changes to weather impacts rather than absolute risk projections. Whilst these scenarios worked well when introducing the problem and examining the generic vulnerability and resilience of the housing stock (see Jones et al, 2013 for further details), the lack of probability risk factors associated with the different scenarios limited their credibility when trying to prioritise adaptation actions. The lack of projected climate risk data must be addressed if real advances in adaptation planning are to be made.

Whilst the toolkits developed to assess the impact of flooding (and overheating) on a range of archetypal properties worked well, allowing 'potentially at risk' properties to be clearly identified and generic adaptation solutions to be evaluated, the level of data required by the toolkits was significantly greater than that which existed within the RSLs built asset management database (step 4). As such re-survey work (internal and external) had to be undertaken to identify the potential impacts that flooding (and overheating) would have on the performance of a range of property archetypes before indicative adaptation solutions could be identified and evaluated (step 5). Going forward the additional data needed for adaptation to climate change should be gathered as part of the routine stock condition survey process.

Whilst the RSL had a clear understanding of its performance criteria through its 'Performance Standard' translating this into generic adaptation principles (step 6) and strategic level thresholds that trigger inclusion of an adaptation into their built asset management plans (step 7) was more complicated than had originally been considered. For example the RSL had a number of basement flats that were at risk from pluvial flooding. Whilst the initial approach to adaptation (from the performance standard) was to make these properties resistant to flooding, it became clear through the study that such adaptations would be uneconomical to achieve. As such a compromise threshold was agreed for these properties to allow them to flood but improve their resilience to speed up recovery. Initially the RSL were very concerned that this approach would be interpreted by tenants as a 'don't care' attitude (contrary to the Performance Standard Principles) and as such they added a non-technical adaptation to work closely with tenants in the potentially 'at risk' properties to explain how they will support tenants through a flooding event. This included working with tenants to help them develop personal flood plans; providing support to allow tenants to protect valuable items; and having robust relocation plans in place.

The other problem with setting meaningful priority thresholds (step 7) and developing adaptation plans (steps 8 and 9) was the lack of quantifiable (probabilistic) projected weather impact data and the numerous gaps in building data meant that only the most obvious adaptations were prioritised for action with the vast majority of adaptations being put 'on hold' until better information is available or until the future risk became obvious. As such, the adaptation strategy can best be described as cautious and reactionary. This approach is at odds with the need to accelerate adaptation of the existing built environment (IPCC, 2014b).

6. Conclusions

This project sought to integrate a theoretical adaptation framework with a performance based built asset management model to provide an approach by which Facilities Managers could develop short, medium and long term climate change adaptation plans. The project has described how a series of performance toolkits can be used to identify potential impacts of climate change on the performance of a house and how triggers and thresholds based on an organisation's CSFs can be used to prioritise interventions as part of routine maintenance and refurbishment planning. Although developed for housing the 10 step model should be applicable to most property types.

Whilst the underlying theory and the assessment tools developed in the project worked well, some of the underlying data required to support the tools was lacking or incomplete. As such, working assumptions had to be made that reduced the level of detail and confidence that Facilities Managers had in the final adaptation plans. At the time of this project there was no consistent UK wide data on the future impact that climate change could have on physical performance of the building stock. Most flood maps that were available didn't accommodate climate change scenarios and, in the case of pluvial flooding, didn't map future rainfall predictions onto local drainage topology. As such the future flooding scenarios lack the currency associated with existing fluvial flood assessment. Where there are accepted climate change models, organisations asset management databases don't generally contain the level of building detail required to develop adaptation solutions. Whilst these issues do not undermine the development of the adaptation strategy, they will influence attitudes towards adaptation planning, resulting in a wait and see approach which is at odds with the needs to plan for the implications of climate change. Better national and organisational data sets are needed to address this shortcoming.

Finally, whilst the technical approach described in this paper worked well, it was developed within a mature (in climate change adaptation and mitigation terms) organisation that had previously assessed its vulnerability, resilience and adaptive capacity to respond to potential climate change threats (see Jones et al, 2013). The approach may not be as easy to replicate for organisations who have not gone through this process. Also, it should always be remembered that it is people who are ultimately affected by the impacts of climate change and more work does need to be done to understand the factors that affect an individual's vulnerability and resilience. In this study no account was taken of vulnerable people living in vulnerable houses.

7. Acknowledgements

The authors would like to acknowledge the support of the Engineering and Physical Sciences Research Council who funded the initial study (Grant Number EP/F035861/1) that developed the theoretical model on which this work was based and the Technology Strategy Board (Project Number 13839-86229) who funded the development of the adaptation strategy.

The Construction Project Manager’s OSH Responsibilities

Abstract

The role of Project Manager is central to a successful safe and healthy execution of any construction project. While there are specific statutory obligations placed on various duty holders across the entire construction process, from the Client through to the worker, it is a core responsibility of the Project Manager to ensure that the hazards that exist in construction do not present harm to the workers and anyone else affected by the construction activity. There are ample sources of advice and guidance available. The Institution of Civil Engineers works closely with Health and Safety Executive in UK and in Northern Ireland to ensure that the highest possible standards of health and safety are developed, promoted and adhered to. This clearly should come within the ethics reasoning of any professional.

This paper introduces key aspects of safety, health and welfare in construction with particular emphasis on project management. The practice based paper examines how the project managers responsibilities developed under the previous (2007) CDM regulations and how these duties are impacted under the CDM 2015 and the proposed CDM (NI) regulations.

Keywords: Construction Design and Management (CDM), Operation Analysis and Control (OAC), Clients, Designers, Principal Contractors, CDM Coordinators, Health and Safety File

1.Introduction: Principles of Health and Safety

Robens (1972) in his report, presented to Parliament by the Secretary of State for Employment stated that “…the first and perhaps most fundamental defect of the statutory system is simply that there is too much law” and in an attempt to simplify the situation recommended a self-regulating system of safety and health provision, where industry and commerce are encouraged to address their own safety and health issues, supported by a single enabling act and a series of appropriate standards and voluntary codes of practice. Much has happened since then but Robens’ fundamental concept holds true. Self-regulation is crucial to good health and safety management and while the influence of Europe has resulted in the introduction of several regulations since the early 1990s the focus in the UK remains consistent.

The core legal requirement for employers is to ensure, so far as is reasonably practicable, the health, safety and welfare at work of all their employees. The parent law is supplemented by regulations, approved codes of practice and guides that provide specific details on how that duty may be met in regard to particular work operations and industries. Across Europe the basic premise in construction safety legislation is that projects should be designed so that they can be built, used, maintained and demolished in a manner that does not cause harm to the workers or others who come in contact with them and that is the essence of the UK's Construction (Design and Management) Regulations (CDM). For many years legislators have been intent upon creating the conditions whereby risk in the workplace would be eliminated. However despite the existence of our present laws, the introduction of new laws such as CDM 2015, and the continuing implementation of supplementary regulations and codes of practice, workplace accidents continue to occur unabated, albeit with a decreasing rate of incidence. However it is not the standard of the law that causes accidents in the workplace. The state aims to eliminate workplace accidents and ill health and many safety professionals understand that to be the intent behind risk management. Yet the mistaken notion has grown up around safety that risk management simply means reducing risks to 'an acceptable level'. This is far from being the intent of legislation since the legal requirement is to secure the health safety and welfare of persons at work through the provision of safe working environments and products. Additional new laws are not needed to control the construction industry, but rather a reexamination of what exists with a view to managing things better. What is needed is a dynamic management model, focused on the elimination of or control of hazards that can produce significant improvements.

Failure to comply with statutory requirements is a criminal matter and the reverse burden of proof placed on a defendant (i.e. the need to prove your innocence), a peculiarity of H&S legislation, emphasises the importance of being able to identify and control hazards throughout the construction process and of being aware of and implementing guidance and good practice (Metherall 2015). This approach is broadly similar across European Union (EU) member states, since much of the present day H&S legislation is derived from EU Directives. A more detailed discussion of H&S law and how it relates to the construction industry is given in the ICE Manual of Health and Safety in Construction (McAleenan and Oloke, 20105).

2.Safer and Healthier Workplaces

It is not just the law that requires that employers and employees have due regard for the potential for harm, inherent in work activities. One of the three paradigms in the Seoul Declaration (ILO et al 2008) refers to the 'prevention culture' indicating that "...it needs to be supported and sustained by shaping and implementing OSH policies, strategies and programs fully reflecting preventive measures". Furthermore the OECD Principles of Corporate Governance state "…boards are expected to take due regard of, and deal fairly with … stakeholder interests, including those of employees, creditors, customers, suppliers and local communities". Therefore there is a moral, legal and principled obligation to manage construction projects in a manner that will not only prevent harm or injury but also protect others from it and this obligation extends to design quality; that combination of functionality impact and build quality that incorporates the key requirements of all the stakeholders, business and whole-life value in relation maintenance, management, flexibility, health and safety, sustainability and environmental impact (Office of Government Commerce, 2004).

Many workplaces are safer and healthier today not simply because of legislation but as a result of the efforts of workers, engineers, safety professionals, legislators and philanthropists. However with 2.3 million dying each year because of workplace accidents and ill health (International Labour Organisation (ILO) 2008) it cannot be asserted that work in general has become safer. There is still a way to go. It is now common in safer workplaces for risk and hazard assessment to be part of good work practices. Metherall (2015) stated that what matters "…is that construction work is organised and done safely" and it is here where the role and the focus of the Project Manager needs to dominate. Knowledge and understanding of the safety legal framework is secondary but that knowledge can help identify what steps must be taken. Metherall (2015) further indicated that the legal framework based on self regulation rather than prescription, has a tiered approach moving from the general obligation in the Health and Safety at Work Act 1974 (Health and Safety at Work (Northern Ireland) Order 1978) to provide and maintain plant and systems of work that are (so far as is reasonably practicable) safe and without risks to health, through to regulations, then to Approved Codes of Practice (ACoPs) and Guidance and finally to the development of good practice.

It is true that construction sites are hazardous environments, with high consequences should control measures be omitted or fail. The Health and Safety Executive (HSE) recognise the main causes of harm in construction as; falls from heights (33% of construction industry injuries), struck by object (13%), and slip, trips and falls (27%), (HSE 2015a, 2015b). Additionally there are health issues such as exposure to harmful agents (such as asbestos and silica), vibration, noise and manual handling (HSE 2015a). Gibb (2015) describes occupational health (OH) as "the poor relation of occupational safety" and goes on to describe OH as "a slow accident". Ill health continues to kill and disable significant numbers of construction workers and the delay in the outworking of the effects is one of the main reasons why the subject must be taken seriously. The major point of concern is that Project Managers are less clear in their understanding of their role regarding the prevention of ill health than they are about safety and this has got to be corrected. Gibb (2015) describes in great detail the various OH issues and the actions that designers and project planners can take to eliminate or reduce ill health effects from the construction process. But the existence of hazards does not make the industry dangerous. There needs to be a negative act or omission before the harm is realised. Every incident represents a loss of control of the work operation. Whether that loss of control can be attributed to the individual worker, or to a Project Manager, at the highest levels of the planning and design stage of the project is not so important as establishing how and why it happened and putting plans in motion to ensure that there isn't a recurrence.

The normal understanding of the word accident is referring to something specific that was unforeseen, unpredictable and/ or an unusual occurrence with no apparent cause. In construction where a Project Manager has a sound and thorough knowledge of the site, the project and the construction processes involved and having analysed the range of operations, identified the hazards and established the necessary controls it is not acceptable to contemplate unusual incidents with no apparent cause. At this point it is worth establishing that accidents don't just happen, rather they are the result of failures in the control process and that should never happen in a well managed project. But Projects Managers cannot deliver a safe and healthy project in isolation, it requires a team effort where they, their site supervisors and the workers control and influence safe and healthy progress, each according to their level of competence and authority, (Maharaj et al 2012, Postman and McArthur 2015).

3.Health and Safety Roles and Responsibilities

3.1.Health and Safety Executive

Great Britain and Northern Ireland's Health and Safety Executives are each "…an independent prosecuting authority who take action against those who put workers at risk of death, illness or injury" (HSE 2010). Among other things they;

- Advise on legislation,
- Produce approved codes of practice and guidance,
- Regulate and enforce compliance with health and safety legislation,
- Investigate workplace fatality, injury and illness incidents,
- Maintain workplace fatality, injury and illness statistics, and
- Carry out appropriate scientific research

3.2.Project Managers

Lingard and Rowlinson (2005) identified construction as a project-based industry and discussed the need for an appropriate structure to deal with the changing nature of the project. As it moves "...from design to construction to in-use phases, and as problems arise there is a need for rapid, decentralised decision-making, contingency planning and an appropriate, organic form of organisation". This engenders a free, independent spirit among construction site personnel and here Lingard and Rowlinson (2005) caution that this freedom could lead to "a disregard for authority and regulations". Such a warning is one that a Project Manager needs to be clear about since he gives both safety guidance and direction in the construction phase of any project. The lessons learned from safety failures in Nuclear Newbuild (e.g. Flamanville 3 NNB in Maharaj et al 2012) post to the need to establish project teams and high calibre managerial and engineering people … and led by a person with the authority to act, (Maharaj et al, 2012). The attitudes and behaviours displayed on construction sites are largely down to the drive and determination of the Project Manager to get the job done well and done safely. Project Managers are key to ensuring that corporate safety and health strategies are delivered at the site level and the culture is one of caring and support for the entire workforce. Therefore where accidents or incidents occur it is crucial that the safety health and welfare of the workers are uppermost in the considerations of the entire management structure, with work progress coming in behind, at a judicious interval.

3.3.CDM Roles

The CDM regulations define the roles and responsibilities of some, not all of the players in construction projects. In the legislation Clients, Designers, Contractors, Workers (and in Northern Ireland, CDM Coordinators) are all given specific legal duties. A short synopsis follows;

3.4.Clients

Clients are required to assess the competence of those they engage to execute a construction project, provide designers and contractors with pre-construction health and safety information (the information that will assist in determining inherently safer design solutions and construction phase safe working methods and resources), ensure that appropriate project health and safety management arrangements are in place before projects commence and where projects are notifiable (longer than 30 days or more than 500 person days of construction work) appoint a Principal Contractor and a CDM Coordinator.

3.5.Principal Designers

A principal designer must plan, manage, monitor and coordinate the pre-construction phase of a project, taking into account the general principles of prevention to ensure that the project pr ogresses without risks to health and safety. The PD must ensure that appropriate assistance is provided to the client in the preparation of pre-construction safety information that includes the identification and elimination or control of hazards likely to effect workers carrying out the construction phase. The PD has the additional duties to ensure the cooperation of all persons working on the project and to ensure that the designers are aware of and are complying with their duties under the regulations, this includes an on-going liaison with the Principal Contractor for the duration of the project.

3.6.Designers

Designers are required to check that project clients are aware of their CDM statutory obligations, be satisfied that they have the competence to undertake the design, consider the pre-construction information and design the project in a manner that it can be built, used maintained and eventually demolished without causing harm to workers or other affected by the structure or building.

3.7.Principal Contractor

The principal contractor is the Project Manager for the construction project and as such is required to plan, manage and monitor the construction phase to ensure that health and safety is appropriately delivered throughout. There can only be one principal contractor therefore ensuring that the other contractors and the workforce are engaging with and coordinating their project health and safety activities are his responsibility. The Project Manager, on behalf of the principal contractor should ensure that the construction phase plan is followed and that any information required for the Health and Safety File is collected and made available before the project hand-over. HSE (2010) describes the Health and Safety File as follows;

"...the file will contain information necessary for future construction, maintenance, refurbishment or demolition to be carried out safely, and is retained by the client or any future owner of the property. (Where a client gets non-notifiable work done, and a health and safety file already exists for the premises, it should be updated if necessary). The file should be a useful and valuable document for the client".

3.8.CDM Coordinator (NI only at the date of writing)

The CDM Coordinator is appointed where projects are notifiable. Their primary role is to give advice and assistance to Clients. Additionally they are to ensure that health and safety has been adequately addressed in the design phase, collect pre-construction information to be made available to the principal contractor and where there is more than one designer they are to check that they are cooperating and coordinating their design information. They do not have a role in site management and during the construction phase their involvement is limited to collection of information for the Health and Safety File and ensuring health and safety is considered, should any redesign take place.

Health and Safety Executive (2007) and Oloke (20105) describe the CDM roles in greater detail.

4.Effective Project Management

Effective project management is concerned with controlling the operation, the process and/ or the system in order to achieve its objectives. The extent to which it succeeds is directly linked to the degree of management effectiveness, which must be focussed on the outcomes rather than simply the processes and methodologies. It must recognise and respond appropriately to factors that impinge upon the outcomes and ensure that the desired outcomes are attained and the principal that management is solely concerned with outcomes falls short if the outcomes are defined purely in terms of product. They must be defined in the wider quality assurance terms that include quality of product, cost effectiveness of production, health, safety and welfare of and appropriate remuneration for workers, safety of customers, sustainability and organisational profitability. The correct activities are those that control the operation properly to achieve the right outcomes. However, where risk exists, control is weakened because risk means that there is a possibility that harm may result; in essence risk exists where there is ignorance of (or choosing to ignore) some or all of the facts and it isn't known with absolute certainty whether the operation will succeed or fail. Every action will therefore have an outcome that is either desired or undesired and a managed operation is one in which all of the hazards have been considered and the controls have been put in place so that the operation itself is free from risk. By effectively managing the operation, concern can then be focused on the reliability of the control mechanisms rather than the probability of exposure to the hazard itself (Gerry Ayers, Australian Construction Safety Professional, in private correspondence with the authors (2002))

Whereas 'risk' is a subjective measure of the possibility of danger being realised, management is the authoritative control of operations, a critical aspect of the Project Manager's responsibilities. The purpose behind the Operation Analysis and Control (OAC) model (McAleenan and Oloke, 2015) is to ensure that work operations are carried out in strict accordance with all relevant 'safe working' procedures. In this way, with high quality planning and implementation you can make sure that people, plant and property are protected from harm prior to, during and after the work operation, regardless of the nature of the hazards faced. Planning any project without reference to the safety requirements means that the project will fail, certainly and, often, spectacularly. Effective management requires that safety is considered as an integral aspect of the project, central to and fully integrated with the project objectives. What a good planning process delivers is consideration of the objectives as well as the means and the methods of achieving them. All elements of the project and every eventuality are considered, in advance and appropriate actions developed and scheduled. Anything that is left out, by accident or by design exposes the project and the company to risk and consequently the likelihood of an undesirable outcome. It is here where the twin survival objectives come strongly to the fore, that is; where workers safety (survival of the individual) and company profitability (survival of the company) co-exists (McAleenan and McAleenan 2010).

In defining the outcomes, and all the relevant considerations the OAC approach requires the identification of the principal actors necessary for the establishment, development and successful achievement of the project. The competence and expertise of a wide range of personnel are needed to input to the various aspects of the project, to establish the parameters of what is achievable within the constraints of finance, engineering & technical capabilities, environmental management, and human interaction before, during and after the project. There will be contradictions between the demands of the various elements that will require expertise to not only resolve them effectively, but to identify and define them in the first instance. The health and safety input will not be derived solely from Health and Safety professionals, but must also come from experienced and competent managers and supervisors, engineers, specialist experts and of course the workers and their representatives. Effective management and operation analysis and control require that those involved in the project will have a contribution to make to the elimination or control of hazards and this applies equally where a client engages a contractor. The client needs to ensure that all relevant H&S information is made available to the contractor and that time and resources have been suitably budgeted for. Similarly the contractor must demonstrate competence to carry out the work; such competence extends to having adequate funds, time and other necessary resources.

5.Discussion, Risk assessment – Process or Product?

In 1997 a NI government agency began the process of implementing the OAC approach to safety management, the underpinning assumption being that every work operation that was not fully controlled was heading for failure, whether in reduced quality or output, plant failure or worker injury. Their approach re-integrated H&S into the process, into individual competence and also required co-operative effort between all the various departments in order to achieve successful production. Crucially OAC took into consideration worker competence, recognising that the competent worker is one who is fully aware of the hazards and the H&S issues within their own sphere of competence and who is capable of assessing and making appropriate decisions with regard to their work activities. This shifted decision-making and control of work operations back into the hands of the worker and the competent team. Superfluous decision makers were removed from the process and those who were left co-operated in the achievement of the objectives, e.g. the production department determined the outputs, engineering the competency requirements, human resources recruited and trained competent workers, finance ensured that the activities were adequately resourced and the operational team determined the requirements of and carried out the work operation, (McAleenan and Oloke, 2015).

The risk assessment approach is not without its critics and opponents. The pre-2010 UK Government established a parliamentary committee (WPC 2008) to look into the problems caused by the risk assessment approach, particularly that aspect that led to the profusion of paper based assessments that workers seldom read much less adhered to, and also the claim that ridiculous decisions were being made, (e.g. councils banning hanging flower baskets for fear that they will fall on the heads of pedestrians). In his submission to the Work and Pensions Parliamentary Committee McAleenan (2008) identified that the risk-averse culture prevalent in Great Britain, stemmed from a misinterpretation of the statutory requirements, which had never been corrected. Now the 2010-2015 government, following a review by Lord Young (2010) to see if the H&S legislation is the cause of such nonsensical decisions appointed Professor Lofstedt to consider what changes may be made to the legislation to reduce the burden on employers (Löfstedt 2011). It is worthy of note that the now defunct CDM ACoP was ahead of such reviews when it stated "…paperwork which adds little to the management of risk is a waste of effort, and can be a dangerous distraction from the real business of risk reduction and management" (HSE 2007).

Some employers see the safety component of work as an additional cost, which can be jettisoned when business is suffering as a result of local or global economic downturn. This unfortunate situation occurs when H&S is perceived as an adjunct to rather than an integral aspect of worker competence. The defunct CDM ACoP (HSE 2007) held that the integration of health and safety into the management of the project is the key aim of the regulations. At the launch of the Seoul Declaration (ILO et al 2008) a number of the platform speakers and signatories highlighted this very point, namely that globalisation and (at that time) the looming economic crisis has serious negative consequences for the health, safety and welfare of workers. The negative health effects of the economic climates since 2008 has impacted most severely on psychosocial risks with mental ill health increasing throughout that period, (van Stolk et al, 2012). (In discussing risk averse companies and the potential consequences McAleenan and McAleenan (2010) introduced the concept of calculating a safe flight distance (Dawkins 2009) or the point at which it is safe to commence the work activity to health and safety, stating that;

"The risk-averse company faces extinction in the marketplace and for the company that ignores risk, their extinction comes at the hands of the courts. The successful company survives because it has evolved a balanced dynamic between productivity and hazard control in which the twin objectives of worker safety (survival of the individual) and profitability (survival of the company) co-exists".

Greenman, Fire Engineering instructor, Bates College, Tacoma, USA in a private correspondence with the authors (2010) commented that workers tend to think only in terms of food on the table, management on profits and so each forgets that their goals are dependent on each other's. The calculation of the flight distance must aim to achieve both worker's and manager's objectives, recognising that an acceptable risk is one that does not conflict with either, (Figure 1).

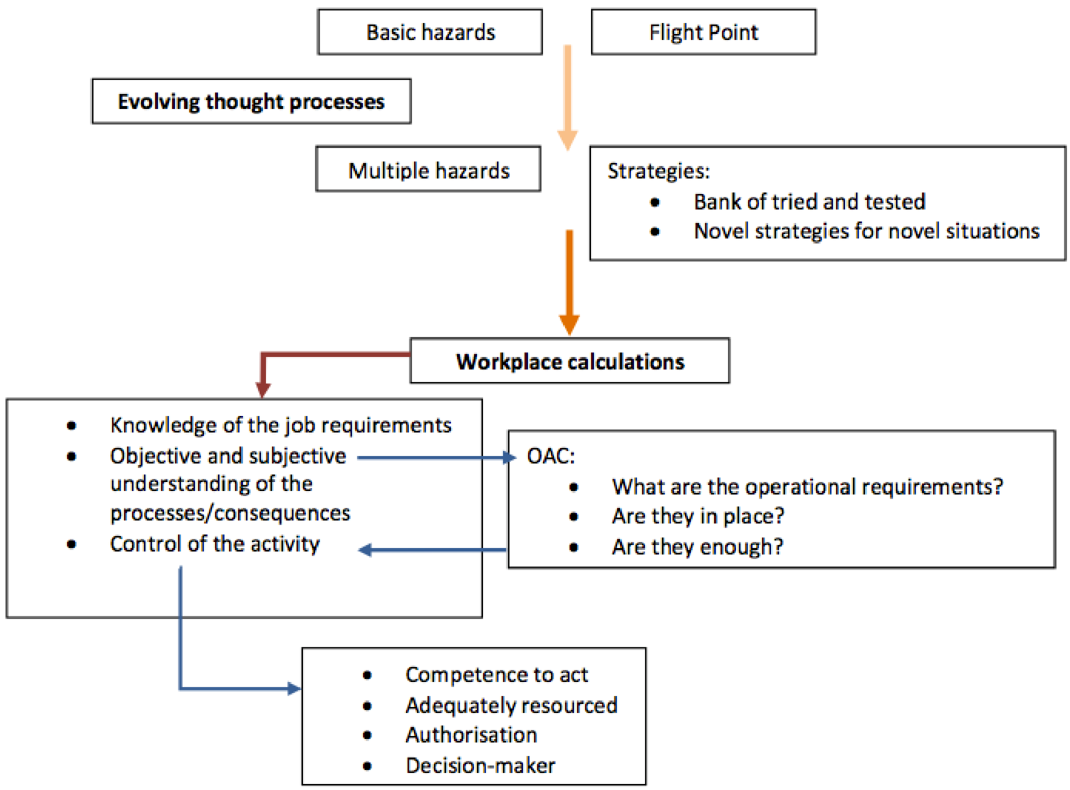

Figure 1: Calculating your Flight Distance (McAleenan and McAleenan, 2010)

6.Conclusions

Orr (ICE Past President, 2007-08) issued one strong piece of advice (in: McAleenan and Oloke,2010), which is echoed by all of the construction professionals who contribute to the ICE's body of health and safety expertise and specifically the Expert Panel on Health and Safety. As construction professionals we all have core values and an ethical position that demands we have a sound knowledge of health and safety within our chosen field of construction and maintain a high regard for the consequences of our professional activities on the safety of workers and others affected by our work, which means;

- Working with integrity;
- Tackling only the work we are competent to do;
- Acting always in the public interest; and
- Continually developing our knowledge.

Project Managers following these principles can ensure that health, safety and welfare is at the heart of everything that is done on a construction project.

Abstract

Electrical and Mechanical (E&M) installations are indispensable to any construction projects. In the light of number of workers and companies involved, E&M works play an important role in the construction industry. The objectives of this study are to reveal causes of accidents of E&M works and provide recommendations to improve safety and health of E&M practitioners. A systematic approach with multidisciplinary inputs will lead to the formulation of a series of holistic and practical measures. An investigation in "WiseNews", a comprehensive newspaper search engine, shows that there were at least 60 E&M works related fatal cases between 1998 and 2014 in Hong Kong. Fatalities due to fall of person from height and contact with electricity account for over 70 % of all occupational fatalities in electrical and mechanical installations. The study also found that the proportion of occupational fatalities due to fall of person from height is occurred more frequently in air-conditioning installation trade. Focus group meetings with frontline workers and experts will identify the root causes of the E&M accidents. Structured interviews will solicit views of different stakeholders to formulate safety preventive measures. NVivo, which is a software package that supports qualitative and mixed methods research will be used to analyse the qualitative data obtained from the interviews. A questionnaire survey will validate and prioritize the causes of accidents and strategies for improving E&M safety. The proposed study will be useful in improving the safety performance of E&M practitioners in Hong Kong.

Keywords: Electrical and Mechanical, Safety, Electrocution, Fall of person from height

1. Introduction

Electrical and mechanical (E&M) installations are significant to most construction projects regardless of new construction works or repair, maintenance, alteration and addition (RMAA) works. E&M works consist of various specialist trades such as fire services installation, electrical wiring, plumbing and drainage, air-conditioning installation, and lift and escalator installation. With the presence of ageing buildings which lack of proper maintenance, the deterioration of fire services, water pipes and electrical wiring in old buildings commonly occurs. To uphold the ageing building stock properly and enhance public safety in a sustainable way, the Hong Kong SAR government has initiated the

Mandatory Building Inspection Scheme (MBIS) in 2012 to inspect and repair these ageing buildings on a regular basis. Around 2,000 target buildings would be selected by the government for inspection and for owners to carry out corresponding repair and maintenance works each year. The scope of inspection is not only limited to the structural elements of buildings, but also the fire safety elements and drainage system. Thus, it is expected that the volume of E&M RMAA works will continue to increase.

E&M installation involves a considerable number of workers. As shown in Table 1, the number of persons directly engaged in “building services installation and maintenance activities” in 2013 was 73,165, accounting for nearly 40% of the number of persons directly engaged in “all construction activities” (n=185,773) (Census and Statistics Department, 2014). The data are also plotted as illustrated in Figure 1. Statistics of number of persons directly engaged in building services installation from 2007 to 2013 also show that the employment of E&M workers has continued in an upward trend (Figure 1). The number of “building services installation and maintenance activities” establishments in 2013 was 7,075, accounting for 32% of the number of establishments of “all construction activities” (n=22,312) (Census and Statistics Department, 2014). The gross value of construction works performed (HK$'000) increased by 17% from 236,926 in 2012 to 278,175 in 2013 whereas the gross value of building services installation works (HK$'000) expanded by 25% from 50,567 in 2012 to 63,089 in 2013 (US$1=HK$7.8). The importance of E&M works to the construction industry of Hong Kong is expected to increase further.

Table 1. Statistics for building services installation activities in Hong Kong (Census and Statistics Department, 2014)

Industry /Group	Year	Number of establishments	Number of persons directly engaged	Gross value of construction works performed (HK$'000) (US$ 1 = HK$ 7.8)
Building services installation (including New works and RMAA activities)	2013	7,075	73,165	63,089
	2012	7 282(-10.1%)	73 828(+1.9%)	50,567,303(-6.2%)
	2011	8 096 (+16.1%)	72 434(+37.5%)	53,916,770(+36.2%)
	2010	6 976 (-13.7%)	52 664(+10.1%)	39,595,569 (+11.9%)

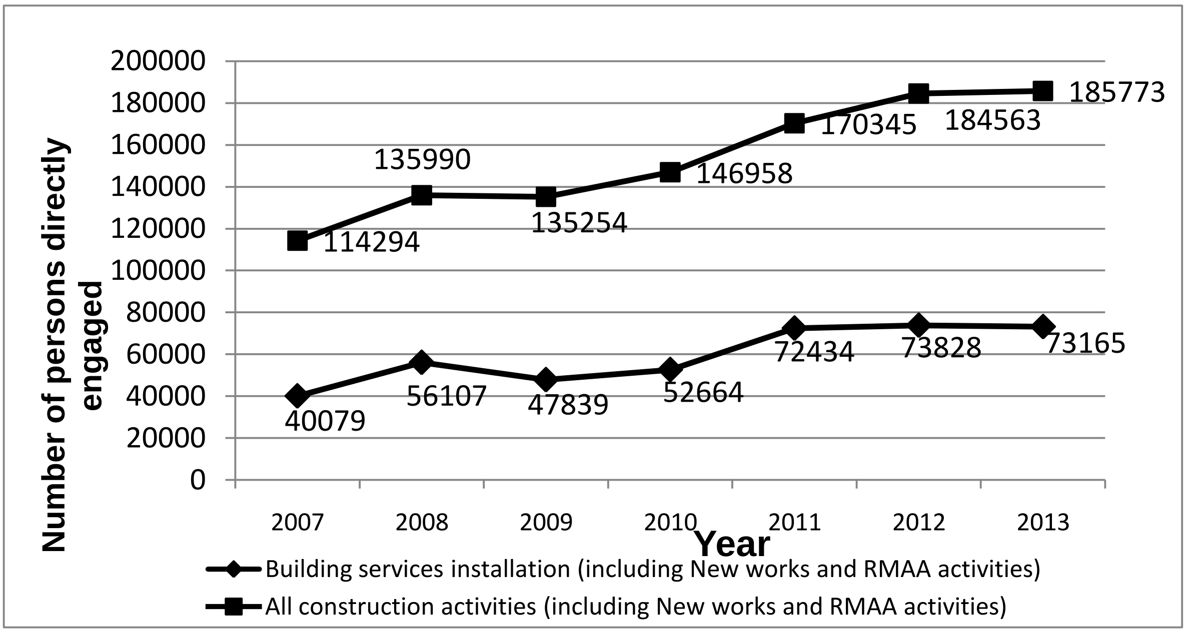

Figure 1. Number of persons directly engaged in construction activities and building services installation in Hong Kong (Census and Statistics Department, 2014)

2. Research Aim and Objectives

Safety issues of E&M works are critical in the construction industry because of the hazardous work nature, tight working schedule and complexity of work. Previous statistics have manifested that falls of person from height and electrocution are the top two killers on E&M works in Hong Kong. There are some detailed analyses of construction fatalities on fall accidents (Huang and Hinze, 2003; Chi et al., 2005; Chan et al., 2008; Hon and Chan, 2013), struck-by fatalities (Hinze et al., 2005), electrocution (Janicak, 2008; Chi et al., 2009) and crane related fatalities (Beavers et al., 2006; Tam and Fung, 2011) etc. Safety research focusing on E&M work installations has been scant. It has not received sufficient attention. The proposed research aims to reveal the causes of accidents on E&M works and provide recommendations to improve the safety and health of E&M practitioners, particularly for those two accident types. To achieve the research aim, four specific research objectives were set out as follows.

1. To understand the general practice and procedures in E&M installation.
2. To determine the causes of E&M accidents.
3. To identify effective measures to be implemented in order to reduce E&M accidents on construction sites.
4. To give recommendations to various stakeholders to enhance E&M installation safety.

3. Significance and Value of Research

The Hong Kong Federation of Electrical and Mechanical Contractors Limited (HKFEMC) which is a sizeable E&M works trade association, has long identified safety a key issue to address (Lam, 2006). HKFEMC has expressed serious concerns for safety of their member practitioners in different occasions. The safety of E&M works has not been given enough attention it deserves. Some hazards associated with E&M works are identified in activities that involve working at height, electricity, lifting, and lift or escalator machinery. Most of the maintenance activities for air-conditioning and plumbing & drainage need to be carried out at height outside the external wall of a building. This greatly increases the likelihood of fall of person from height. Moreover, there are some risks, like electrocution perhaps is significant at E&M works. The study will provide insights to root causes of both fatal and non-fatal accidents of E&M works. The overall aim is to investigate the major causes of E&M works related accidents and recommend a series of practical and holistic measures to reduce them. It is important to upkeep construction workers' safety and health. Improvement in the safety of E&M works will benefit not only the practitioners themselves but the industry as a whole.

4. Research Methods

A mix of qualitative and quantitative research methodology has been employed in this project. The whole research process comprises seven key stages: (1) literature review, (2) focus group meetings, (3) case studies, (4) structured face-to-face interviews, (5) questionnaire survey, (6) data analysis and (7) validation of the results. The research framework for the proposed study is shown in Figure 2.

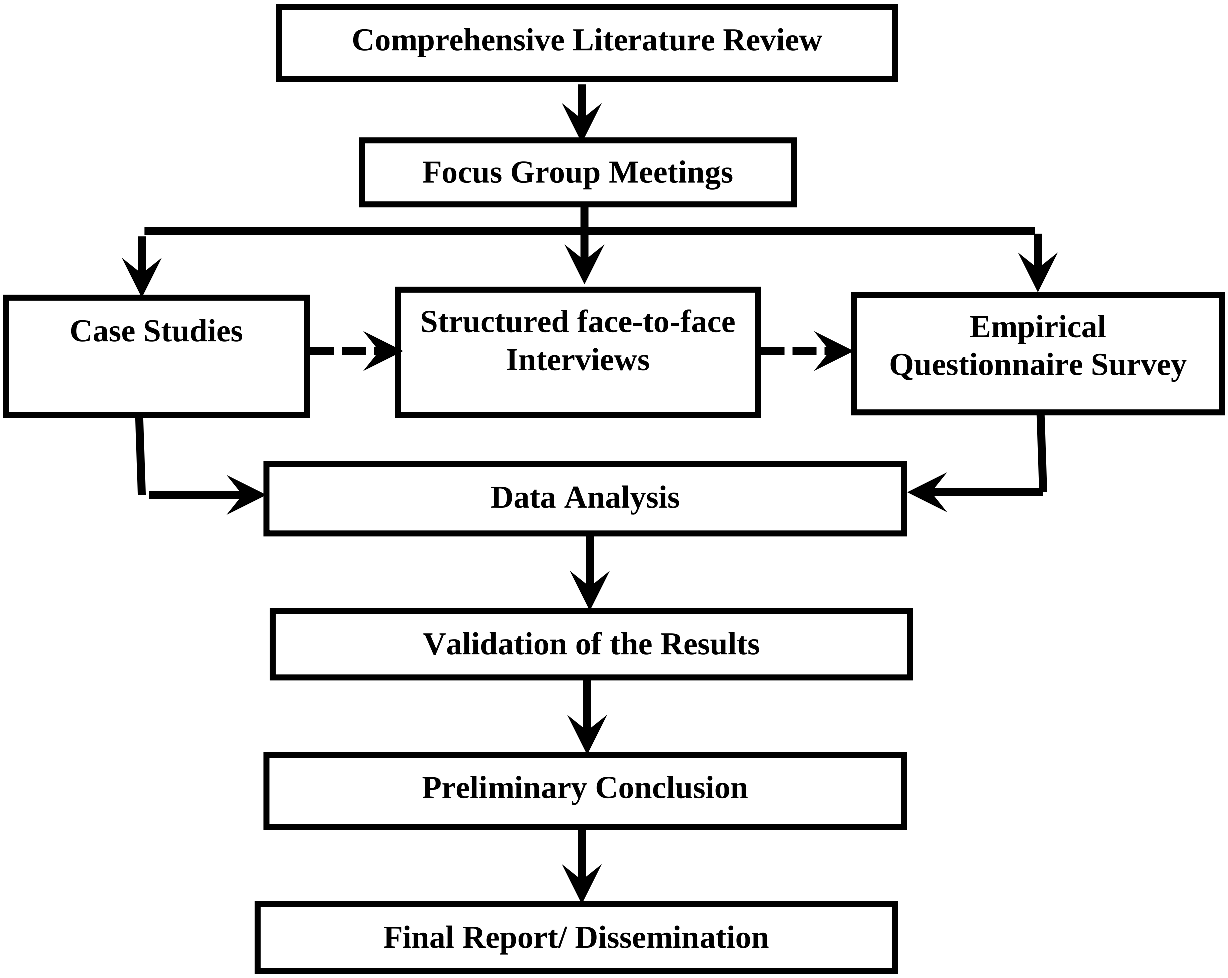

Figure 2. Flow of the Overall Research Framework

5. Research Progress and Preliminary Findings

Literature review

The research project began with a comprehensive review on general practice and safety procedures in E&M installation and common causes of E&M works related accident and safety research on E&M works from academic journals, industry report, research monographs, guidance notes, and newspaper, etc. An extensive review of related ordinance, code of practice, safety working guidelines from six government departments or organizations including the Construction Industry Council (CIC), Labour

Department, Occupational Safety and Health Council (OSHC), Buildings Department (BD), Hong Kong Housing Authority (HKHA) and Electrical and Mechanical Services Department (EMSD) has been launched to capture common types of E&M accidents, major causes of E&M accidents and recommendations on E&M works.

Accident statistical data in Hong Kong will be collected from government departments (including the Architectural Services Department, Census and Statistics Department and the Labour Department) and the volume, nature and the patterns of E&M works related accidents will be examined. The review will focus on safety problems and good practices of E&M installations which will form the foundation for the whole research.

Focus Group Meetings

Two focus group meetings were conducted with (1) trade unions' representatives and frontline tradesmen, and (2) representatives from the Hong Kong Federation of Electrical and Mechanical Contractors Limited (FEMC) in October and December 2014 respectively. It aims to examine the safety problems and the major causes of accidents. Focus group meetings are considered a convenient and effective way of collecting a large amount of information supplementing the traditional one-to-one interview (Haslam, 2003) because it generates synergism and stimulation among attendants (Vaughn et al., 1996). Their expertise has been drawn upon to give comments on safety issues on E&M works, to indicate the root causes of E&M accidents from their practical experience and contribute to the formulation of preventive strategies and measures. Focus group meetings provided a general picture of the safety problems of E&M works and also helped in developing templates for structured interviews and questionnaire surveys.

Case Studies

Both fatal and non-fatal E&M accidents will be retrieved and reviewed. Information on fatal cases will be solicited from relevant government departments and further supplemented by the "WiseNews" newspaper archive which is an electronic search engine containing key local newspaper clippings (Hon and Chan, 2013). These cases will be categorized according to characteristics and features. Key categories may include (1) year and month of accidents; (2) location of accidents; (3) type of work involved; (4) trade of work involved; (5) type of accidents; and (6) any other special features. Fatal cases collected from various sources will be triangulated and cross-referenced to ensure accuracy and reliability of the raw data. The study requires support of the industry. Sources of non-fatal accident cases for analysis could be obtained from member contractors of the Hong Kong Federation of Electrical and Mechanical Contractors Limited (HKFEMC), the Electrical and Mechanical Services Department (EMSD), the Architectural Services Department (ArchSD), and the Hong Kong Housing Authority, etc. Root causes of E&M fatal and non-fatal accidents will be identified respectively.

As official accident statistics on E&M works are not readily available in the public domain, an extensive search in "WiseNews", which is an electronic database of local newspapers in Hong Kong, was conducted. The results show that there were at least 60 E&M works related fatal cases between 1998 and 2014 in Hong Kong. Approximately two-thirds of the 60 fatal cases were related to RMAA works. There were 39 E&M works related accident cases occurred in RMAA works which far outweighed that of new construction works (*n=21*). Fatalities due to fall of person from height and contact with electricity account for over 75% of all occupational fatalities in the electrical and mechanical industry. Among various E&M trades, air-conditioning installation is the most common trades leading to fatality. This trade accounted for a total of 33% of all E&M works related fatal cases (Figure 3). This may be due to the fact that air-conditioning works extensively involve working at height outside the external wall. This greatly increases the likelihood of fall accidents.

With the consent of the Coroner's Court, 13 case files of E&M fatalities between January 2010 and July 2013 have been collected for detail analysis. Each case file include information on police investigation files, coroner's death investigation reports, fatal accident reports by the Labour Department, autopsy reports and medical reports. The advantages of referring to the coroner's reports are that the data is highly reliable for revealing the real causes behind an accident.

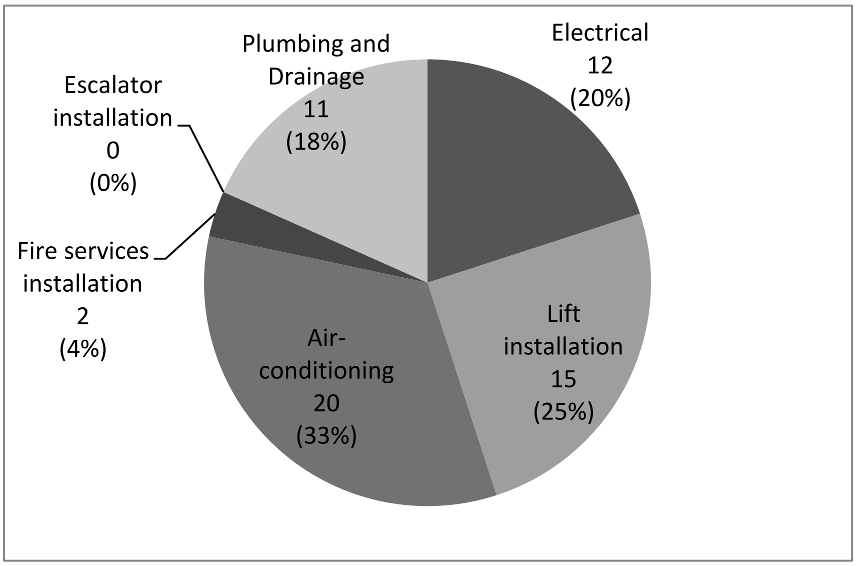

Figure 3. E&M works related fatal accidents from 1998-2014– analysed by Trades (Sources: WiseNews)

Structured interviews

Ten structured interviews have been conducted with key trades of E&M installations, including air-conditioning, fire services, plumbing, and electrical works. Interviewees include representatives from the government, quasi-government organizations, professional institutes, contractors' associations, and trade unions. Interview questions are compiled based on the literature review and also the results of the focus group meetings. It designed to identify the causes leading to common E&M accidents and strategies for improving safety of E&M work practitioners. The interviews results has been transcribed, coded and analysed in NVivo, a software system for analysing qualitative data. Mixed methods research qualitative data will similarly be collected, organized and analysed (Creswell, 2009). Basically, common interview narrative subjects and similar semantic meanings are first coded in individual category. After that, each identified category will then be compared with other categories and repeat this coding process for refinements to better arrive at distinct categorization.

Based on the ten structured interviews of E&M works practitioners, fall from height and electrocution have been identified as the top two killers in both new and repair, maintenance, alteration and addition (RMAA) E&M works in Hong Kong. The major causes of new E&M works and RMAA works are "Compressed working schedule & long working hours" and "Lack of facilities for safe access or improper design for maintenance" respectively.

Questionnaire survey

A questionnaire survey will be designed based on literature and findings from the case studies and structured interviews. The previous qualitative interviews can be used as an exploratory step before designing the questionnaire survey form. Respondents will be requested to prioritize the causes of E&M accidents and importance of recommendations for enhancing E&M works safety. About 200 number of completed questionnaires will be targeted to facilitate quantitative statistical analyses. Questionnaires will be dispatched via industry forum and presentations. The advantages of conducting questionnaire survey in this way are that respondents can get immediate assistance from investigators of the proposed studies and thus improving quality of their responses. Also, respondents attending the industry forum have interests in E&M safety. They are more likely to give reliable and informed responses based on their working experience and expertise.

Data analysis

An Excel template with predetermined categories will be decided for the analysis of case studies (Hon and Chan, 2013). The cases will be coded in the EXCEL template and analysed with SPSS. Descriptive statistics will be utilized in analysing accident records pattern. Key coded variables include year of accident, month of accident, type of accident and trade of E&M works etc. Some fatal and non-fatal accident cases will be selected for detailed analysed. Cluster analysis will be employed to classify types of E&M fatal and non-fatal accidents respectively (SPSS, 2001; Hon and Chan, 2013).

Descriptive statistics and multivariate statistics will be used for analysing questionnaire data using Statistical Packages for Social Science (SPSS). Kendall’s coefficient of concordance (W) will be adopted to measure the levels of agreement of experts (Siegel and Castellan, 1988). Spearman’s rho correlation (Norušis, 2008) will be calculated to assess the degree of correlation among the opinions expressed by groups of experts. The Kruskal-Wallis Test, which is regarded as a non-parametric test will be conducted to decide whether three or more independent groups are from distinct populations.

6. Conclusions

Hong Kong is a populous city with a multitude of ageing and deteriorated buildings. It is crucial to inspect and repair these buildings on a regular basis. E&M installations involve a considerable proportion of all practitioners in the RMAA sector. Repair and maintenance of air conditioning systems and water pipes are highly related to working at height. Fall injuries frequently happen when using ladders and majority of the injured workers are unskilled labourers working on a temporary basis. Electrocution is also a major type of E&M related accident. A person who has been electrocuted may be severely injured or even die. This research project provides an overview of E&M works related accidents in Hong Kong, identify underlying causes of accidents and practical recommendations through a series of research tools including focus group meetings, cases studies, structured interviews and questionnaire survey. The project has begun for about a year and is still ongoing. Case analysis, focus group meetings and interviews have largely been completed. The next step is to collect holistic opinions from E&M works practitioners by questionnaire for improving safety performance of the E&M industry.

Acknowledgements

This paper forms part of the Construction Industry Council (CIC) funded research project entitled "Electrical and Mechanical Safety in Construction" with several research objectives sharing common background of study and research methodology.

Abstract

In Hong Kong, safety performance of the construction industry has substantially improved since the late 90s. However, this improvement in terms of accident rate and fatality number has slowed down and reached a plateau after 2006. The purpose of this study is to evaluate the safety awareness and behaviour of construction practitioners at various levels. Construction practitioners were classified into five levels as CEO, project management team, supervisors/foremen, trade-specific foremen, and frontline workers based on their different roles in construction site safety. Semi-structured interviews were conducted to assess the safety awareness and behaviour of CEO, project management team, and supervisors/foremen. Questionnaire survey was conducted to assess the safety awareness and behaviour of trade-specific foremen and frontline workers. A total of 280 construction practitioners participated in this survey, including 6 CEOs, 6 project management team leaders, 8 supervisors/foremen, 28 trade-specific foremen, and 232 frontline workers. It was found that construction practitioners across different levels possessed a satisfactory level of awareness and behaviour on safety with those at the frontline level having a comparatively lower score for safety awareness and behaviour. It is recommended that training, instructions, and remarks should be given for safety improvement at various levels.

Keywords: construction industry, Hong Kong, safety awareness, safety behaviour, safety culture

1. Introduction

Construction is a large, complex, and dynamic sector that generates employment for millions of people worldwide. However, this sector has high number of fatalities and non-fatal occupational injuries and illnesses (Hoonakker et al. 2005). Improving site safety is a top priority for construction companies throughout the world (Choudhry et al., 2007). Having a mature and positive safety culture is becoming crucially important to facilitate safety improvement (Choudhry et al., 2007).

The construction industry is one of the economic pillars which contributes about 4.0% of Gross Domestic Product (Census and Statistics Department, 2015) and 8.2% of total working population in Hong Kong (Labour Department, 2015). According to the occupational safety and health statistics of 2013, there were a total of 3,232 industrial accidents from the construction industry, 2.3 per cent up when compared to 3,160 in 2012 (Labour Department, 2014). Furthermore, the safety performance of the construction industry in Hong Kong lags behind as compared with nearby Asian cities, such as Singapore. The accident rate per 1,000 construction workers in Hong Kong was 41.9 in 2014 whereas the accident rate per 1,000 construction workers in Singapore for major injuries and minor injuries were 0.41 and 5.20 respectively (Legislative Council 2015). Although the Hong Kong SAR (Special Administrative Region, China) government has stipulated construction related safety and health legislation to reduce the accident and fatality rate, there are still a lot of rooms for improvement. Cultivating a good organizational safety culture is considered to be an effective way for further improvement (Zou 2011).

Safety culture is shaped by people working together in organizational structures and by social relationships in the workplace. It is recognized that leadership is important in the creation of a culture that supports and promotes a strong health and safety performance of an organization. Leaders play a key role in the creation of safety climate, which in turn influences workers to increase their safety behaviours, thereby decreasing their accidents and injuries (Hoffmeister et al., 2014). Managers and /or the team leaders are vital in inspiring employees to a higher level of safety and productivity, which means that they must apply good leadership attributes on a daily basis (Flynn and Shaw, 2010).

In Hong Kong, an annual Construction Safety Week (CSW) is organised by the Development Bureau (DevB) and the Construction Industry Council (CIC) to promote health and safety to all stakeholders of the construction industry. As one of the key initiatives of the CSW, the organizers commissioned the authors to undertake a research study to investigate and further enhance the safety awareness amongst the key stakeholders of the construction industry. The objectives of the study included: (a) classify the practitioners of the construction industry into a number of levels based on their different roles in construction site safety; (b) establish guidelines to enable the practitioners to become safety leaders in their corresponding levels; (c) monitor / gauge the enhancement of safety culture in the construction industry.

2. Five Levels of Construction Practitioners

Effective leadership can improve safety performance in hazardous and complex working environments (Flin and Yule 2004). An extensive literature review of construction practitioners' values, attitudes, perceptions, and patterns of behaviour at various levels were conducted. Previous studies related to this research are consolidated, thereby enriching the understanding of current knowledge. The literature was sourced from government/industry reports, books, and top-tier journals (Biggs et al. 2008; Choudhry et al. 2007; Clarke 2013; Conchie et al. 2013; Cooper 2000; Fernández-Muñiz et al. 2007; Flynn and Shaw 2010; Flynn and Yule 2004; Hoffmeister et al. 2014; Kines et al. 2010; Krause and Weekley 205; Koch 2013; Lu and Yang 2010; Martinez-Corcoles et al. 2011, 2013; Martin and Lewis 2014l Mohamed 2003; O'Dea and Flin 2001, 2003; Ostrom et al. 1993l Wamuziri 2006, 2013; Wu et al. 2008, 2011; Zou 2011). As illustrated in Table 1, construction practitioners are classified into five levels according to their roles in construction site safety. The roles of construction practitioners at each level are shown in Table 1:

Table 1 Five (5) levels of construction practitioners

Level	Position	Role
1	CEO	drive strategic decision
2	Project Management Team	involve in all project related issues
3	Supervisors and Foremen	supervise and arrange the construction materials and the labors at project level
4	Trade-specific supervisors	supervise and arrange the construction materials and the labors at trade level
5	Frontline worker	operate specific task

3. Data Collection

Semi-structured interviews and questionnaire survey were conducted to assess the current level of safety culture in the Hong Kong construction industry. Construction practitioners at various levels (i.e. CEO, project management team, supervisors/foremen, trade-specific foremen, and frontline workers) were invited to participate in this study. Face-to-face interviews were conducted with construction practitioners from Level 1 to 3, including 6 CEOs, 6 Project Management Team Leaders, and 8 Supervisors/Foremen. Questionnaire survey was conducted with trade-specific supervisors and frontline workers. A total of 28 valid questionnaires from Level 4 and 232 valid questionnaires from Level 5 were collected respectively. The participants were asked to evaluate their safety awareness/consciousness and actions/behaviours in day-to-day operations. They were asked to rate the level of agreement on the awareness/consciousness based on a 5-point Likert scale (i.e., 1 represents "strongly disagree" and 5 indicates "strongly agree"), and the actions/behaviours based on a 5-point Likert scale (i.e., 1 represents "always don't" and 5 indicates "always do"). The participants from Level 1 to 3 were also asked to rank the relative importance of factors contributing to positive safety culture. The factors contributing to positive safety culture were identified in the literature (Biggs et al. 2008; Feng et al. 2014; Wamuziri 2006, 2013; Chen et al., 2013; Choudhry et al. 2007; Zhang and Gao 2012; Zou 2011). All the data collected are treated in strict confidence by the research team. Both quantitative and qualitative analyses were employed to analyse the empirical data in this study.

4. Results and Discussion

4.1 Level 1 CEO

Ratings on safety awareness and safety behaviour in Level 1 are illustrated in Table 2. The respondents are strongly realize the importance of safety. Only the mean score on "all accidents can be prevented" is less than 4.5. Regarding the safety behaviour, the mean scores are between 4 and 5. It is found that "proactive action will bring about changes in safety behaviours and performance" is relative low with the score of 4.17.

Table 2 Ratings on the safety awareness and safety behaviour in level 1

Safety awareness	Rating
Everyone shares a responsibility on safety	5
The company shoulders a social responsibility on safety	5
All accidents can be prevented	4
Safety is an integral part in business performance	5
Safety behaviour	
Establish a clear mission, safety responsibility system and goal in order to set standards of behaviour for employees	4.83
Work with subordinates to reinforce the corporate safety commitment	4.83
Be clear and transparent when dealing with safety issues	4.67
Ensure statutory compliance with government health and safety regulations	4.67
Share the beliefs of the project management team	4.33
Proactive action will bring about changes in safety behaviours and performance	4.17

The participants were asked to rank the relative importance of factors contributing to positive safety culture. It is found that "provides resources to support safety", and "formulates safety policies to reflect the beliefs" are the top two important factors contributing to positive safety culture at Level 1 CEO.

4.2 Level 2 Project Management Team

Ratings on safety awareness and safety behaviour in Level 2 are illustrated in Table 3. Regarding the safety awareness, the mean scores on both "Shares the CEO's belief" and "worker safety is first priority" are 4.67. The mean score on "proactive action will bring about changes in safety behaviours and performance" is 4.33.

The mean score on "positive and proactive action will bring about changes in safety behaviours and performance" is 4.33. Regarding the safety behaviour, the mean scores on most items are between 4 and 5. It is found that the respondents performed worse in the "drive for the flexibility and adaptation of safety management" with the score at 3.67.

Table 3 Ratings on the safety awareness and safety behaviour in level 2

Safety awareness	Rating
Shares the CEO's belief	4.67
Safety is a core element of project management	4.67
Positive and proactive action will bring about changes in safety behaviours and performance	4.33
Safety behaviour	
Motivate the workforce to participate in safety activities in order to increase their awareness of safety and acceptance of safety responsibility	4.5
Allocate resources to safety management commitment	4.67
Reinforce/support subordinates' safety activities	4.5
Organize safety training and promotion	4.83

Keep safety rules and regulations updated regularly	4.83
Promote ‘Safety Behaviour’ campaigns	4.83
Establish effective incentive schemes and reward systems to reinforce safety behaviour	4.5
Express appreciation and respect for good safety behaviour	4.83
Encourage the workforce to rectify the risky behaviour when they disobey safety rules	4.83
Emphasize the interests in acting on safety policy	4.67
Apply the rules and company safety policy consistently	4.83
Address safety system flaw, be willing to admit mistakes and correct them	4.67
Drive for the flexibility and adaptation of safety management	3.67
Communicate with the subordinates on safety behaviours	4.33
Advocate and communicate safety values to subcontractors	4.33
Review safety process and take feedback seriously	4.17

The participants were asked to rank the relative importance of factors contributing to positive safety culture. It is found that “enhance safety knowledge”, and “instil respect and commands authority” are the top two important factors contributing to positive safety culture at Level 2 Project Management Team.

4.3 Level 3 Supervisors/Foremen

Ratings on safety awareness and safety behaviour in Level 3 are illustrated in Table 4. Regarding the safety awareness, the mean scores on both “shares the beliefs of the project management team” and “worker safety is first priority” are 4.67. The mean score on “proactive action will bring about changes in safety behaviours and performance” is 4.33. Regarding the safety behaviour, the mean scores on most items are between 4 and 5. It is found that “provide subordinates with a flow of challenging and innovative ideas for improving safety” is relatively low with the score at 3.67.

Table 4 Ratings on the safety awareness and safety behaviour in level 3

Safety awareness	Rating
Shares the beliefs of the project management team	4.67
Worker safety is first priority	4.67
Proactive action will bring about changes in safety behaviours and performance	4.33
Safety behaviour	
Consider the hazards and risks before and during the execution of any task	4.5
Take necessary precautions to mitigate these risks	4.5
Review safety process and take feedback seriously	4.5
Provide safety equipment to the workforce	5
Explain the concept of safety and good practices clearly	4.67
Stop any unsafe activity or operation	4.83
Be consistent and fair in dealing with workers against safety issues	4.67

Listen to workers' concerns with regard to safety and act on them	4.50
Be willing to admit mistakes and correct them	4.67
Report all unsafe conditions, practices and all injuries and illness	4.67
Report the risk assessment regularly	4
Conduct safety site-walks and report and rectify any irregularities	4.33
Detect and correct errors based on monitoring subordinates' safety behaviour or being reported by the subordinates	4.33
Coach, mentor, and provide feedback promptly	4.33
Build strong relationship with frontline workers	4.33
Provide subordinates with a flow of challenging and innovative ideas for improving safety	3.67
Deliver the established incentives and punishments as part of the daily routine	4
Lead investigations into injuries, accidents and high potential incidents	4
Provide feedback and follow up near-miss and post-accident reports	4.17

The participants were asked to rank the relative importance of factors contributing to positive safety culture. It is found that "carry out risk assessments before work", and "give safety instructions and information along with work instructions" are the top two important factors contributing to positive safety culture at Level 3 Supervisors/Foremen.

4.4 Level 4 Trade-specific Foremen

Ratings on safety awareness and safety behaviour in Level 4 are illustrated in Table 5. Regarding the safety awareness, the mean scores on "worker safety is first priority" at 4.75, which is higher than that on "proactive action will bring about changes in safety behaviours and performance" and "shares the beliefs of the project management team" at 4.39 and 4.18 respectively. Regarding the safety behaviour, it is found that the respondents performed worse in "provide inputs for design for safety", "report the risk assessment to superiors regularly", "deliver the established incentives and punishments as part of the daily routine", and "provide subordinates with a flow of challenging and innovative safety ideas", with the score at 3.73, 3.90, 3.90, and 3.90 respectively.

Table 5 Ratings on the safety awareness and safety behaviour in level 4

Safety awareness	Rating
Shares the beliefs of the project management team	4.18
Worker safety is first priority	4.75
Proactive action will bring about changes in safety behaviours and performance	4.39
Safety behaviour	
Consider the hazards and risks before and during the execution of any task	4.20
Take necessary precautions to mitigate these risks	4.03
Provide safe equipment to workers	4.43
Detect and correct errors based on monitoring subordinates' safety behaviour or being reported by the subordinates	4.13

Stop any unsafe activity or operation	4.43
Coach, mentor, and provide feedback promptly	4.20
Carrying out safety induction/familiarization training	4.40
Ensure that plants and equipment are being licensed, registered, and maintained regularly	4.13
Report all unsafe conditions, practices, near-misses, injuries, and illness	4.33
Comply with all safety policies, procedures and rules	4.37
Ensure workforce to obey/enforce safety rules	4.20
Monitor worker's awareness of safety instructions regularly	4
Trust and respect frontline workers	4.33
Be consistent and fair in dealing with workers against safety issues	4.30
Be willing to admit mistakes and correct them	4.3
Provide inputs for design for safety	3.73
Report the risk assessment to superiors regularly	3.90
Deliver the established incentives and punishments as part of the daily routine	3.90
Provide subordinates with a flow of challenging and innovative safety ideas	3.90

4.5 Level 5 Frontline Workers

Ratings on safety awareness and safety behaviour in Level 5 are illustrated in Table 6. Regarding the safety awareness, the mean scores on "safety is everybody's responsibility and each one has a part to play" and "personal safety at work is utmost concerns to one's family and friends" at 4.46 and 4.43 respectively, which are higher than that on "all accidents can be prevented" with the score at 4.20. Regarding the safety behaviour, it is found that the respondents performed worse in "make suggestions and initiate new ideas to supervisor proactively", "participate in safety activities", and "communicate with fellow-workers on health, wellbeing and safety issues regularly" with the score at 3.91, 3.94, and 3.97 respectively.

Table 6 Ratings on the safety awareness and safety behaviour in level 5

Safety awareness	Rating
Safety is everybody's responsibility and each one has a part to play	4.46
Personal safety at work is utmost concerns to one's family and friends	4.43
All accidents can be prevented	4.20
Safety behaviour	
Commit to use safety equipment provided	4.23
Perform work in accordance with safety practices and safety procedures	4.25
Report all injuries, illnesses, near misses, equipment damage, unsafe conditions, and practices to the superiors promptly	4.16
Advise and remind fellow-workers who deviate from safe working practice or misbehaves in safety	4.11
Reinforce and influence safety behaviour in workplace constantly	4.26
Work with management to identify safety problems and find solutions	4.03
Keep abreast of new knowledge	4.07

Participate in safety activities	3.94
Communicate with fellow-workers on health, wellbeing and safety issues regularly	3.97
Make suggestions and initiate new ideas to supervisor proactively	3.91

5. Conclusions

In Hong Kong, the safety performance of the construction industry has substantially improved since the late 90s. However, this improvement slowed down and reached a plateau after 2006. Having a mature and positive safety culture is becoming crucially important to facilitate such an improvement. This study aims to evaluate the performance of safety leadership scheme in the Hong Kong construction industry. Construction practitioners were classified into five levels as CEO, project management team, supervisors/foremen, trade-specific foremen, and frontline workers based on their different roles in construction site safety. Beliefs, initiatives, guidelines on being a "Safety Pioneer" for each level of construction practitioners were established. Semi-structured interviews and questionnaire survey were conducted to assess the safety culture in the local construction industry. A total of 280 construction practitioners were participated in this survey, including 6 CEOs, 6 Project Management Team leaders, 8 Supervisors/Foremen, 28 Trade-specific Foremen, and 232 Frontline Workers.

Findings of the research study indicated that: (a) construction practitioners at all levels possessed a satisfactory level of awareness/consciousness and actions/behaviours on safety; (b) construction practitioners at lower level tended to have a comparatively lower score for safety awareness and behaviours; (c) areas for further improvement includes: (1) "drive for the flexibility and adaptation of safety management" at Level 2 Project Management Team, (2) "provide subordinates with a flow of challenging and innovative ideas for improving safety" at Level 3 Supervisors/Foremen; (3) "provide inputs for design for safety", "report the risk assessment regularly", "deliver the established incentives and punishments as part of the daily routine", and "provide subordinates with a flow of challenging and innovative ideas for improving safety" at Level 4 Trade-specific Foremen; and (4) "participate in safety activities" "communicate with fellow-workers on health, wellbeing and safety issues regularly", and "make suggestions and initiate new ideas to supervisor proactively" at Level 5 Frontlines worker; (d) the main benefits of safety leadership scheme includes "minimize the work-related accidents on site", "a powerful influence on promoting the safety culture because initiated by the government", and "set clear expectation and can be measurable". Based on the above findings, it is recommended that training, instructions, and remarks should be given for safety improvement at various levels.

A limitation of the study is the limited sample source and sample size. In this study, participants at Level 1 CEO, Level 2 Project Management Team, and Level 3 Supervisors/Foremen were mainly from large-sized enterprises. Further research work should be done to increase the sample size and to replicate the survey to small and medium-sized enterprises (SMEs). The present study examines the current status of safety awareness and behaviour at various levels of construction practitioners. Similar studies should be carried out in regular basis to monitor the enhancement of safety culture in the construction industry.

6. Acknowledgements

This project is funded by the Development Bureau of the Hong Kong Special Administrative Region, China and the Construction Industry Council. The research team is indebted to the support from Paul Y Engineering Group Limited, Yau Lee Holdings Ltd., Leighton Asia, India, and Offshore, Chun Wo Construction Company Ltd., Dragages Hong Kong Ltd., Wan Chung Construction Co. Ltd., Sanfield Engineering Construction Ltd. and Sanfield Building Contractors Ltd. In particular, the participation of CEOs, project management team members, supervisors/foremen, trade-specific foremen, and front-line workers in this survey is gratefully acknowledged.

Causes of Risk Misallocation in the Zambian Construction Industry

Chipozya Kosta Tembo and Nthatisi Khatleli

Construction Economics and Management, University of the Witwatersrand
Email: Chipozya@yahoo.co.uk

Abstract

Risk misallocation has been a concern in the construction industry globally due to its resultant effects of quality shortfall, disputes, claims, cost and time overruns. Various studies have focused on the identification of misallocated risks and how a project team can rectify the problem. However, the current discourse does not address the causes of misallocation. This research is aimed at bridging that gap by establishing why risks are misallocated in the construction industry, with the Zambian building sector as a focus. The study used heterogeneous purposive sampling to select professionals in the Zambian construction industry for semi-structured interviews. The professionals selected had over ten years' experience in the building sector and had worked on building projects with various peculiarities. Various causes for misallocation were identified, and these were divided into three main categories, namely, work environment related, worker related and work related. Work environment factors include available contract forms; data, information and feedback, and contract conditions; worker factors include lack of perception and knowledge, inadequate skills and training and poor understanding of the consequences of risk; work related factors include the rationale for risk allocation and available response mechanisms. The identification of causes of risk misallocation helps the client to better understand how risk allocation can be enhanced in the construction industry; this is a positive step toward reducing misallocation and improving project performance in the construction industry. The research highlights the need for the construction industry to have diverse contracts, favourable and enabling contract conditions and workers with the necessary skills and understanding of the consequences of unmitigated risk among the contracting parties. Contractor and client as the contracting parties also need clear knowledge and perception of risks in addition to adopting a rationale for risk allocation that is not only based on responsibility but also ability to manage.

Keywords: Risk misallocation, buildings, causal issues, Zambia

1. Introduction

A construction project of any magnitude or nature is normally faced with a variety of risks. These risks could be market related, environmental, economic, financial, social, legal, technological, political, technical or physical (Sharma & Bhatnagar, 2006). The generic understanding of risk is that it is an event or occurrence that negatively impacts project performance (Flanagan & Norman, 1993; Smith, Merna, & Jobling, 2006). However, risk can also be construed as an event or occurrence that can impact project performance positively or negatively (Hilson, 2002; PMI, 2004). Caño and Cruz (2002) define *risk* as "an uncertain event that, if it occurs, has a positive (opportunities) or negative (threats) effect on a project objective" (p. 473). The way in which risk is managed can result in either threats or opportunities. It is during the risk management process that liability for risk, commonly known as *risk allocation*, is assigned. This is normally done in the risk response stage. A risk response measure could be an alternative procurement method, a construction method or material, monitoring, the use of insurance or bonds, contingency (time or money), subcontracting or even collaboration (Bakr, Khaled, & Ayda, 2012; Loosemore and McCarthy, 2008; Serpella, Ferrada, & Rubio, 2014; Smith, Merna, & Jobling, 2006; Uff, 2010). In architectural and engineering projects the allocation of risk is done through the standard form of contracts. Contracts allocate risks by providing for future contingencies with varying degrees of specificity (Triantis, 2000). Nevertheless, it is not uncommon for the standard forms to have modifications (Mooney & Mooney, 2013) resulting in either unbalanced risk allocation or more equitable allocation, so when the occurrence of an unforeseeable event would cause a promisor to bear an unexpectedly large loss in performing their contractual obligation, the parties may perhaps renegotiate and modify the promisor's contract (Triantis, 2000).

Various risks have been observed to negatively impact project delivery in the Zambian construction industry, leading to quality shortfalls, as well as cost and time overruns (See Kaliba, Muya, & Sichombo, 2013). In addition, claims in the industry are rampant, with such causes as poor risk sharing and incomplete and incomprehensive contract documentation (Sibanyama, Muya, & Kaliba, 2012). Mukumbwa and Muya (2013) find in their study of unethical practices in the Zambian construction Industry (ZCI) one-sided contracts, where risk is transferred to the contractor, and insertion of unfair clauses which are disadvantageous to the contractor.

This research is aimed at identifying the prevalent risks and the practices that lead to risk misallocation. This has been done cognizant of prior studies which have identified misallocated risks with a view to allocating risks appropriately between the client and contractor. It is important that the causes of misallocation be established if this problem is to be dealt with at the source in the future.

2. Risk Allocation in the Construction industry

Risk allocation is the assigning of management responsibility and accountability for risk(s) (Alsalman and Sillars, 2013). Risk allocation practice in the construction industry has been described as poor, unbalanced, balanced, and from misallocated to inappropriate (Alsalman &

Sillars, 2013; Baloi & Price, 2003; Khazaeni et al., 2012). For risk allocation to be carried out, risk identification, risk analysis and response should be undertaken. Poor risk allocation refers to any instance of misallocation, including incomprehensive allocation of risks (Meng, 2012; Mead, 2007); unbalanced risk allocation refers to allocation of most of the risks to one party without justification (Alsaman & Sillars, 2013; Bakr, Khaled, & Ayda, 2012; Lam et al., 2007); balanced risk allocation refers to liability associated with risk events, and thus possible loss or gain from the project, properly identified and distributed (Khazaeni, el al 2012); inappropriate risk allocation refers to contractual shifting of risk to the contracting party with the least amount of bargaining power (Hanna et al., 2013).

This research defines risk misallocation as the allocation of risks wrongly or inappropriately (Hanna, Thomas, & Swanson, 2013); that is, it refers to any wrong method of allocation and/or inappropriate response method and/or allocation to the wrong party between client and contractor and their representatives and/or allocation of inappropriate resources or lack of allocation. Alsalman and Sillars (2013), using a questionnaire survey, established that when risks are not allocated accordingly they result in disputes, tensions, claims, quality shortfalls and time and cost overruns.

3. Methodology

This study used a qualitative approach to appraise misallocation in the Zambian building sector using a heterogeneous purposive method to select various professionals (engineers, quantity surveyors, architects and procurement officers) in the Zambian construction industry for semi-structured interviews. Semi-structured interviews have been used in related studies (e.g., Goh and Abul-Rahman, 2013; Lehtiranta and Juunonen, 2014). A semi-structured interview is one which has a written set of open-ended or closed questions for use by the interviewer in a person-to-person interaction (Kumar, 2011). The professionals selected had at least ten years of experience in the building sector and had worked on a variety of building projects. The sample was selected from professionals in both public and private sectors; contractors were selected from the building category in grades 1–3. Grade 1–3 contractors are registered under the National Council for Construction (NCC): grade 1 represents the highest contractor grade, those contractors with unlimited capacity; grade 2 is for contractors with a capacity of carrying out projects of up to K25M (US$2M; exchange rate: US1 = K12.5); grade 3 contractors carry out projects of up to K10M (US$0.8M). The grades go up to 6. Grades 1–3 were chosen because 90% of the work in the building sector is done by these contractors, and they are obligated to subcontract 20% of the value of the works to grades 4–6 for public works when necessary. However, maximum contract values of Grade 4 (K5M [US$400,000]), Grade 5 (K3.5M [US$280,000]) and Grade 6 (K1M [US$80,000]) should not be exceeded. The respondents were as follows: 2 quantity surveyors, 2 architects, 2 civil engineers, 2 clients, 2 project managers, 1 contractor grade 1, 1 contractor grade 2, 1 contractor grade 3 and 2 procurement officers, giving a total of 15 respondents (see Table 1 for details).

The interviews to gain insight into issues leading to risk misallocation ranged from about 45 minutes to 70 minutes. Before the interview, permission was sought to audio record, and where the permission was not given, permission was obtained to take notes. Interviews were chosen because they are the best tools for collecting in-depth information (Greener, 2008; Patton, 2002). Semi-structured interviews were preferred because they normally provide uniform information (Gray, 2009). Apart from the ability to collect in-depth information, interviews aid in the generation of historical data (Cresswell, 2007) and provide an opportunity to probe. Other advantages to interviews include these: information can be supplemented, questions can be explained and they can be used in any type of population (Kumar, 2011). Conversely, interviews have the demerit of being time consuming and expensive (Bhattacherjee, 2012; Cresswell, 2007; Gray, 2009; Kumar, 2011). The seven-step procedure outlined by Cresswell (2007) was used as follows: (1) locating an individual, (2) gaining access and making rapport, (3) purposefully sampling, (4) collecting information, (5) recording information (audio recording and/or taking notes), (6) resolving field issues, and (7) storing data. Location of individuals and gaining access was mainly done through their professional bodies. Prior contact was made either by e-mail or phone call to ascertain whether an individual had at least 10 years' experience in building projects. Table 1 shows respondents' years of experience, sector of engagement and nature of building projects worked on. The average in years for the respondents was 17 years. It is quite clear that the years of experience are vast and the nature of building projects provides a good mix for the study.

Table 1: Respondents' characteristics

I.D	***Sector***	***Experience in Years***	***Role in construction***	***Scope of building projects in years of experience***
1	*Public*	*15*	*QS*	*Offices, houses, schools*
2	*Public*	*12*	*Civil Eng.*	*Offices , hospitals, schools*
3	*Public*	*10*	*Procurement officers*	*Offices, houses*
4	*Public*	*20*	*QS*	*Housing units, offices, health facilities, hospitals*
5	*Public*	*19*	*Architect*	*Schools, offices, border infrastructure, houses*
6	*Private*	*10*	*Contractor*	*Houses, student hostels, high rise buildings*
7	*Private*	*32*	*QS/PM*	*Offices, hospitals, residential, banks, filling stations, stadia, factories*
8	*Public*	*21*	*Client org*	*Primary schools, secondary schools, colleges, houses*
9	*Public*	*23*	*PM*	*Prisons, military installations, houses, rural health centers, flight terminal, border facilities, offices*
10	*Private*	*30*	*Eng. Consultant*	*Showrooms, schools, filling station, hospitals hotels, office buildings*
11	*private*	*29*	*Contractor*	*Housing, offices, banks, schools, hostels*
12	*Private*	*10*	*Contractor*	*High schools, maternity wards, student hostels, offices*
13	*Private*	*10*	*Client Org*	*markets, fire stations, bus shelters, houses,*
14	*Private*	*15*	*Procurement Officer*	*Office blocks, houses, farm layouts and different buildings, lodges, banks*
15	*Privat e*	*10*	*Architect*	*Houses, offices, shops, farm buildings, banks*

The analysis was done mainly through content and interpretive analysis. Interpretive analysis aims to capture hidden meaning and ambiguity (Gray, 2009), looking at how messages are encoded, latent or hidden. Content analysis is a research tool used to determine the presence of certain words or concepts within text or sets of texts (Robson, 2011). In some instances, there was a link in the analysis between the current practice and existing theory in risk allocation, namely, transaction cost theory, expectancy theory, principal-agent theory and structuration.

4. Discussion

4.1 Prevalent Risks to Building Projects

Various risks impact building projects, and the following were indicated by respondents as prevalent: late payment (80%); lack of inspection, supervision and monitoring by consultants (73%); poor supervision by contractors (73%); contractor's cash flow problems (73%); lack of adherence to contractual provisions by client (67%); slow decision making by client (60%); bureaucratic processes (60%); frequent changes in material prices (60%); unstable exchange rate (60%); poor workmanship (52%); frequent change in scope (52%). These risks are diverse due to the nature of building projects. Late payment is mainly attributed to poor financial standing of the client, poor budget planning or poor bureaucratic processes. This could be contributing to contractors' poor cash flow.

4.2 Nature of Risk Misallocation in the Building Sector

All respondents, as shown in Table 2, asserted that the allocation of risk is not balanced because contractors are compelled to carry more risks than the client. Additionally, in certain instances, risks which are better shared between the client and the contractor, such as escalation in the cost of materials and unstable exchange rates, are shifted to the contractor. The underlying reason for this practice, as explained by the consultants, was to minimize the cost to the client. It was also clear that certain methods of allocation preferred by the client contributed to misallocation, such as the practice of obtaining bonds from banks only and the allowable level of subcontracting. This was indicated by 60% of the respondents. Some risks were not allocated despite the fact that these are present in the original standard forms of contract which were modified using waiver clauses, leading to some clauses becoming non-applicable. The respondents (60%) suggested that sometimes either the client or the contractor is wrongly allocated a risk resulting from modification of a standard contractual clause, such as the omission of fluctuation and escalation clauses. Lastly, it was also common to allocate resources wrongly due to the underestimation of the scope or nature of the work. This form of misallocation would be mainly in terms of inappropriate finance allocation, as illustrated by 100% of the respondents; insufficient personnel to supervise and monitor the works, as pointed out by 80% of the respondents and insufficient or wrong plant and equipment revealed by 60% of the respondents. This is usually occasioned by incomplete design and a lack of investigation of the site conditions.

Table 2: Nature of risk misallocation in the construction industry

Nature of misallocation	*Frequency*
Unbalanced risk allocation	*15*
Wrong method of allocation	*9*
Risk allocation to wrong party	*9*
Lack of allocation in signed documents	*3*
Inadequate or wrong resources used in allocation (personnel)	*12*
Inadequate or wrong resources used in allocation (plant or equipment)	*6*
Inadequate resources used in allocation (finance)	*15*

4.3 Causes of Misallocation: Work Environment Related

The environment relates to the surrounding conditions in which an employee or organisation operates. It can be composed of physical conditions, such as office temperature, or equipment such as personal computers. However, for this study the environment was used to refer to work processes or procedures as they relate to risk in a project environment. Process and procedures followed on projects that were particularly related to risk allocation were considered. The following were identified as factors contributing to misallocation.

4.3.1 Contract Forms Used

The main contracts in use in the Zambian construction industry are the Zambian Public Procurement Agency (ZPPA) contracts (2013), which include open national bidding, international bidding (FIDIC red book, harmonised 2005 version) and small works contracts, and the Joint Liaison Contract (JLC), commonly known as the ZIA (Zambia Institute of Architects) contract. All the respondents claim that these are almost always modified to accommodate the requirements of the clients or financiers of projects. Occasionally, this leads to allocating most of the risks to contractors. Of the respondents, 60% also indicated that current contracts do not reflect what is needed because they are based on traditional procurement, and in recent times professionals in the industry have had contracts that are design-and-build in nature and feel the current contracts do not seem to address the risks that come with such arrangements. It is important to point out that contracts in use based on traditional procurement do not reflect the risk liability in an integrated system of procurement. The respondents (60%) indicated that there is a need to have a flexible contract or new contract showing the actual risk liability in such an arrangement.

4.3.2 Data, Information and Feedback

Data and information were cited as some of the initial causes of risk misallocation. Designers (architects and engineers) and cost estimators (quantity surveyors) interviewed (60% of respondents), especially those in the public sector, suggest that most of the time they design or estimate projects without going to the site or conducting necessary investigations; this results in inaccurate assumptions of site conditions. Contractors indicated that most of the data they base their tender price on lack detail, especially drawings which had either missing or insufficient detail. Contractors claim they would sometimes tender for projects, especially for public sector projects, without going to the site, making it difficult to quote properly and allocate resources accordingly. There seems to be lack of information and project data for decisions to be made on risk where site conditions are concerned.

Feedback on risks between the contractor and the client once projects have commenced was described as generally poor by 80% of the respondents. When steps were taken to get feedback, the feedback was not given in a timely manner. However, among consultants there seemed to be various methods of feedback on issues to do with risk, such as reports and meetings. It was also noted that contractors who have been in operation for 3 years or more appeared to have the knowledge to query on certain issues which they felt would affect their performance, such as verification of variations and specification, and demand for detailed drawings. Contractors (100%) indicated that the lack of design details and late feedback lead to risk misallocation on their part, especially in the allocation of resources and pricing. Consequently, consultants and procurement officers (73%) from the private and public sectors pointed out that when there was no clarity in a drawing the contractor tends to over-price the work to cover risk. This is expected even more when escalation and fluctuation clauses are omitted in a contract. The latter could be understood as an act by the client or employer to keep transaction cost to a minimum at the peril of the contractor. Nevertheless, in the final analysis, costs are hardly reduced, as alluded to by the consultants, because contractors give fairly high bids, reacting from an expectancy theory viewpoint. Fair bids and contract sums could therefore be attained through the preparation of clear and detailed contract documents.

4.3.3 Contract Conditions

Various contractual conditions which form part of the procedure for practice in the Zambian construction industry could be said to be inhibiting appropriate risk allocation and result at times in either misallocation of resources or formulation of one-sided contracts. The following are practices that seem to be contributing to misallocation.

Sub-contracting. Most contracts carried out in the Zambian construction industry have a level of subcontracting of 20% of the value of the work. For large projects contractors have a mandate to subcontract 20% of the work to medium- and small-scale contractors when necesary. The respondents, especially consultants, indicated that this level of subcontracting is too low, and that those awarded the 80% in most cases do not themselves have the capacity or need to subcontract much more than 20%, and failure to subcontract more than 20% invariably leads to late completion. On the other hand, such specialised works as electrical, plumbing and air-conditioning exceed the 20% threshold and result in works being carried out by the main contracted, who may not be specialised. Using inappropriate subcontracting levels may lead to wrong resource allocation, leading in turn to late project delivery.

Omission of escalation and fluctuation clauses: Contracts over a twelve-month period normally require the use of escalation and fluctuation clauses, mainly to protect the contractor from increased prices. However, in the Zambian construction industry these clauses are omitted or waived most of the time, even for contracts whose duration is over 12 months, resulting in the contractor carrying this risk when it should be covered or shared with the client. This was reported by 93% of the respondents. This, if illustrated from a principal agent point of view, could be said to be spawning opportunistic behaviour by the client (principal), who will be trying to lower costs. However, the contractors proactively mitigate this risk by putting a high mark-up on their bids (expectancy theory). This was alluded to by 73% of the respondents. Nevertheless, this demonstrates that the client has not fully analysed the consequence of this act, which may result in higher costs.

Preferred sources of bonds and guarantees: The Zambian construction industry has traditionally demanded the securing of bonds and guarantees from banks only. However, in the last year all respondents indicated that insurance firms have become acceptable as sources of bonds and guarantees. This is a positive move, ensuring that performance bonds and advance payment bonds are obtained on projects. However, despite this, most clients still insist on bonds or guarantees from banks. Banks need collateral in the form of fixed assets. This in turn reduces the sources of finance for contractors, which normally results in poor cash flow during project execution. This is so because obtaining guarantees or bonds initially from banks lessens the opportunity of this avenue being utilised in the future, as the collateral held by the bank will render a contractor less liquid. This could be minimised if bonds or guarantees are obtained from insurance houses, which usually require payment of premiums, rather than collateral in the form of fixed assets. The majority of the respondents (87%) were of the view that bonds and guarantees obtained from insurance houses afford contractors the opportunity to source additional finance if needed from the bank, unlike when they are initially obtained from the bank. This helps the contractor’s financial management and cash flow and could help cushion the risk of late payment by the client, thereby ensuring that resource misallocation in the form of finance is minimised.

Safety Provisions: One project manager and 1 architect, and 2 of 3 contractors, comprising only 33% of respondents, stated that there seems to be a wrong method of risk allocation associated with safety because the clause is not punitive towards non-compliance. Though the respondents may not be in the majority, they give insight into why accidents are a common feature on construction sites. Consequently, contractors do not comply in terms of providing a safe working environment and provision of proper safety gear for workers on site. The respondents were of the view that if the safety clause were punitive in nature it would reduce the risk of contractors not complying.

4.4 Causes of Misallocation: Worker Related

The *Oxford Learner’s Dictionary* defines a *worker* as “a person that performs a specific or necessary task or who completes tasks in a certain way.” For tasks to be completed successfully workers need to have the necessary skill and capacity to perform the task. For risk allocation or management to be done effectively the skills and capacity of those involved should be adequate (Mu, Chen, Chohr, & Peng, 2014).

4.4.1 Perception and Knowledge

Perception of risks is significant in the consideration of the allocation of any risk. One rarely allocates risk(s) that are perceived to be less important or thought to have a low possibility of occurrence. Most of the respondents (67%) asserted that sometimes risks are not allocated due to lack of perception. In some cases, the resources allocated are not appropriate due to lack of perception or knowledge of an event as being a risk. There was nevertheless unanimity among the respondents that risks that are poorly managed lead to project failure. Giddens (1978) notes in his seminal work that in the duality of structure only a knowledgeable agent can influence structure or perhaps the way risks are allocated. From a structuration theory point of view, lack of perception in the Zambian construction industry of certain risks is leading to misallocation. Agents cannot allocate or monitor what they do not perceive to be a risk.

4.4.2 Skill and Training

Effective carrying out of risk allocation requires that risks be identified, analysed and treated. The majority of respondents (67%) indicated that they have had some training in risk management: some aspects of risk allocation were covered during their tertiary education, during their professional membership registration process or during a workshop or a seminar; the other 33% appear to have had no training at all. When asked the methods they used for risk identification, the majority indicated experience on past projects (62%); others indicated local knowledge (27%) and 33% use checklists. Other methods captured for risk identification included document review, meetings, works task analysis and cash flow analysis. Risk analysis is not actively done in the Zambian construction industry. Experience was indicated by 47% of the respondents as the method utilised for risk analysis, though it is rarely done; others indicated that they do not use any method for risk analysis (53%). For risk response, all the respondents indicated that this is done in the contract documents used. However, given that most contracts are modified and some clauses omitted or waived, risk response and analysis should be undertaken when conducting contract modifications.

4.4.3 Poor Understanding of Consequences of Risk

The majority of respondents (80%) were of the view that most clients as they modify contractual clauses or fail to honour contractual obligations do not fully understand that they allow other risks to occur. Figure 1 shows the risks that were mentioned by various respondents as being unanticipated by clients.

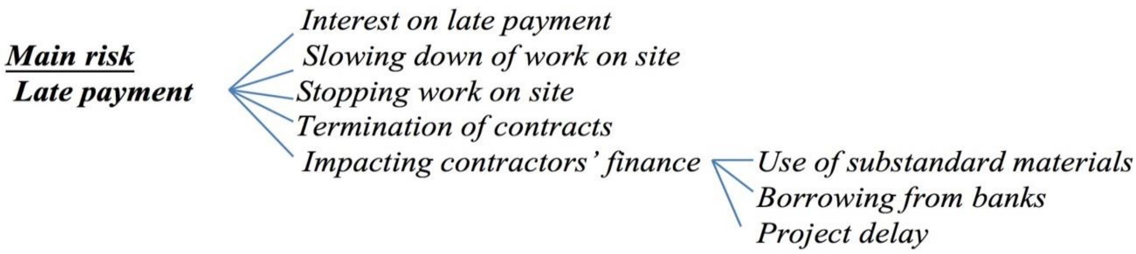

Figure 1. Risks consequential to late payment (respondents' views)

That is, late payment either by public or private clients results in other risks. As many respondents noticed, clients normally foresee paying interest on late payments but not the other risks.

4.5 Causes of Misallocation: Work Related

4.5.1 Rationale for Allocation

The *Oxford Learner's Dictionary* defines *work* as "a task or tasks to be undertaken." In the construction sector various tasks are undertaken by various professionals. Risk allocation on contracts used in the Zambian construction industry is understood to be based on responsibility or role by 67% of the respondents. Other rationales used to allocate risk identified by respondents (20% each) include risk avoidance and management ability. Basing risk allocation on responsibility or role is good for establishing liability, basing on a principal agent reasoning, but it may neglect or lead to misallocation of external risks which are not a direct responsibility of either party. In addition, it may result in risk being allocated to the party least able to manage risk. Moreover, the one whose role includes being responsible for risk is not necessarily the one best suited to manage the risk.

4.5.2 Available Response Mechanism

All types of construction projects have risks, building projects included; uncertainties sometimes lead to risks not being foreseeable. The majority of respondents, especially those in the public sector, are reactive when it comes to risks, and they respond to risk mainly to avoid audit queries and budget overruns (indicated by 60% of the professionals). This leads to misallocation by unfairly allocating risks to contractors. Contractors (100%) in their defence rarely query such allocations for fear of losing work opportunities.

5. Conclusion

Different construction industries in different jurisdictions have peculiar risks impacting on their performance and their own challenges in achieving appropriate risk allocation. Late payment is the most prevalent risk in the Zambian construction industry. Various risk misallocation practices have been found to exist in the Zambian construction industry, such as unbalanced or one-sided allocation, wrong or inappropriate methods of allocation in terms of response strategy used, and use of wrong or inappropriate resources (plant and equipment). Causes of this misallocation have been found to be environmental factors (contract used; data, information and feedback; contract conditions), worker related factors (perception and knowledge, skill and training and poor understanding of the consequences of risk) and work related factors (rationale for allocation and response mechanism). The clients in their preparation of contract documents and conduct of contract administration have been seen to take measures that seemingly reduce costs without considering how the reaction from contractors would impact cost. From an expectancy theory perspective, contractors tend to over-price bids as a response to client omission of clauses and neglect of adherence to contract conditions, such as costs awarded with an extension of time.

It could therefore be concluded that risk misallocation is contributing to poor project delivery in the building sector. The research highlights the need to have diverse contracts, timely exchange of information and data between contracting parties, favourable and enabling contract conditions, necessary skill and understanding of the consequences of unmitigated risk among the contracting parties, clear knowledge and perception of risks and the adoption of a rationale for risk allocation that is based not only on responsibility but also on ability to manage. In addition, flexibility by clients on sources of guarantees and bonds such as insurance companies could help the contractors' cash flow, thereby reducing the risk of late payment. Furthermore, varying the percentages for subcontracting according to project requirements could lead to favourable project delivery. The future focus of this research is to validate these findings through a questionnaire survey and document analysis of contract documents used in the Zambian construction industry.

Abstract

A plethora of studies is found, which investigates physical injuries and health problems in construction. Similarly, numerous models have been developed to date to explain their causes. However, an equally important work health and safety issue, the psychological wellbeing of construction workers, is an under explored area. This research empirically analysed 376 cases of psychological injuries occurred to construction workers and developed a causation model. The study found seven causes that are responsible for psychological injuries amongst construction workers, viz.: (1) workplace harassment and bullying, (2) work pressure, (3) work-life conflict, (4) discrimination, (5) poor physical work environment, (6) job uncertainty and (7) poor workplace relationships. Among these, long sustained workplace harassment and bullying, often accompanied by violence, produces critical psychological injuries that require time-off-work for longer than a year. Similarly, constant work pressure leads to severe psychological injuries that require time-off-work for 100 to 365 days. The study highlights the urgent need to curb workplace harassment and bullying in order to make the construction industry free from critical psychological injuries.

Keywords: Work health and safety, psychological injury, construction operatives, causation model.

1. Introduction

Construction accidents have been explored extensively to date, resulting in several accident causation models. These various models focus on physical injuries and health issues because these are visible to the outer world and loud when occur. Most of the existing safety management strategies and systems too are heavily focused on curbing physical injuries and health problems. An equally important work health and safety (WHS) issue is the psychological wellbeing of construction workers. Because psychological injuries suffered by workers are invisible and silent, unlike physical injuries, they go unnoticed for extended periods, causing serious damages to workers. Hohnen and Hasle (2011) asserted that most employers fail to see the psychosocial injuries endured by workers and current WHS management practices too are heavily focused on technical aspects and neglect psychosocial hazards.

Some previous studies are noted within the broader topic of psychological health of construction workers. Golderhar et al. (1998) examined the impact of sexual harassment, gender discrimination, job uncertainty and over compensation at work on female construction workers' physiological well-being. Golderhar et al. (2003) modelled the relationships between job stressors and accident outcomes in construction projects. Likewise, Siu et al. (2004) investigated relations among safety climate, psychological strains and safety performance in construction projects. Larsson et al. (2008) studied the significance of good psychological climate in construction projects for improved safety outcomes. Leung et al. (2010) identified workplace factors affecting job stress of construction workers and further explored the impact of it on injury incidents. Melia̓ and Becerril (2007) explored how factors such as leadership, role conflict and mobbing behaviours influence workers' psychological health. Most of these studies still placed the focus on accident outcomes and treated psychological symptoms as mediators of physical injuries and health problems. The other studies were narrow in scope, suggesting further explorations are needed to understand and model the realm of psychological injuries of construction workers. To this end, this research aimed at identifying the factors that affect the psychological health of construction workers and mapping them in a causation model.

2. Literature review

Psychological health is defined as a state of mental well-being that influences one's ability to realise his/her potentials and work productively to contribute to the advancement of self and society while successfully managing the stressors of work and life (CSA 2013). Poor psychological health lead to several undesirable behaviour patterns and symptoms in employees, viz.: difficulty to focus on work and to make rational decisions; finding it hard to meet reasonable goals and deadlines; being absent from or late to work frequently; excessive tiredness and fatigue; getting overwhelmed or irritated easily with people or work tasks; displaying negative thoughts and loss of self-confidence; avoiding workplace gatherings such as staff meetings, socialisations, etc.; appearing atypically worried, apprehensive, emotional or tearful; and resorting to alcohol or drugs to cope (Beyondblue 2014).

Unfavourable conditions and/or stressors encountered at workplaces can trigger poor psychological health in employees. Eight such themes were elicited in a critical review of literatures, as discussed below. The literature review provided valuable insights and a solid foundation for the empirical study.

2.1 Work pressure

The inherent nature of construction could exert pressure on site management team and workers as they try to accomplish several tasks concurrently within a limited time and space. Choudhry and Fang (2008) reported that construction workers were constantly instructed by their supervisors to perform the task quickly, which often led to compromising safety for productivity and thereby higher injury rates. This situation causes worker to be under constant job stress. Leung et al. (2010) added that work overload also increases job stress within workers.

2.2 Workplace relationships

Poor support or relationships at workplaces can put a psychological strain on workers (Walen and Lachman 2000). Having a sense of team spirit and developing good relationships with workmates are of significant socio-psychological influencers for workers (Kazaz and Ulubeyli 2007). This creates a harmonious and positive workplace where workers tend to be morally supportive to each other. However, social relationships among co-workers can be a challenging issue for migrant workers. Language barrier is an impediment. Fang and Goldner (2011) argued that local language competency is a determining factor for migrant workers' successful transition into work culture. Moreover, it is directly linked to their economic success, which also influences the psychological well-being.

2.3 Poor physical work environment

Arboleda and Abraham (2004) postulated that being constantly exposed to extreme outdoor temperatures, poor air quality, excessive noise, dirty drinking water, odour, chemicals and hazardous working conditions can induce stress in workers.

2.4 Work-life conflict

Tennant (2001) observed that most adults attain satisfaction in life from work and family; however, these could also be sources of stress if not balanced effectively. Van Amelsvoort et al. (2004) postulated that work-family conflicts often result in inadequate time and energy to fulfil both family and work duties; one of them is likely to be compromised. Bust and Gibb (2006), for example, found that shift work among construction workers created family problems and stress. Moreover, workers with family issues had their work performance affected, which in turn showed repercussions on their economic situations. These factors collectively affect their psychological state (Glasscock et al. 2006).

Overtime work is commonly practised by organisations when a project is behind schedule or faces labour shortages. Overtime can be in the form of extending the daily work hours or rostering weekend work. In construction projects, workers generally cannot opt out overtime work. Long work shifts exceeding 13 hours or continuously working throughout weekends could lead to both physical and mental exhaustion, particularly in difficult conditions like extreme heat or cold (SoialistWorker 2011).

2.5 Workplace harassment and bullying

Mikkelsen & Einarsen (2002) found that exposure to harassment and bullying at work was associated with an increased number of psychological and psychometric complaints. Likewise, Law et al. (2011) found in Australia that 24% of compensation claims in 2007 and 2008 were linked to workplace harassment and bullying. Moreover, gender-based and sexual harassments were identified by Goldenhar et al. (2003) as strong stressors that cause poor psychological wellbeing for women in the construction industry. Severe forms of harassment and bullying are regarded as violence, which are extreme social stressors (Zapf et al. 1996). Leymann (1996) enlisted behaviours that constitute violence at work, which include: social isolation, assigning a person too little or too simple tasks, slander, intimidating or criticising, physical violence and threat of violence, and rumours about one.

2.6 Discrimination

Literature suggests that migrant workers may face discriminatory treatments by employers, local workers and/or unions. Discrimination by employers include unequal wages for the same jobs, offering jobs un-matching their qualifications/skills and limited work hours. Wong et al. (2007) claimed that migrant workers are perceived to be increasing competition in the market, thereby threaten job opportunities for local workers. As such, migrant workers face hostility from locals and at times are linked to increased crime rates in the city. Harcourt et al. (2008) argued that discrimination against migrant workers is not limited to employers or local workforce and pointed out that unions that lobby for restrictions on immigration to satisfy the majority group are hesitant to help ethno-cultural groups to acquire decent work conditions. Depending on the country of origin and economic backgrounds, migrant workers would initially tolerate discrimination. However, over time they experience frustration, feelings of shame, bitterness, strain and loss of sleep (Simich et al. 2006).

2.7 Job uncertainty

Dekker and Schaufeli (1995) found that job uncertainty faced by employees of a transport organisation in Australia was strongly associated with psychological distress. They further argued that the negative psychological effect of job uncertainty extends beyond the potentially redundant employees and affects their families too. Among the organisational practices that pose a sense of job uncertainty are: casual/contract employment, redundancy, gender/ethnic/nationality preferences, etc. Job uncertainty for construction workers is placed in a delicate position. The continuity of construction jobs is heavily dependent on the availability of new projects for the employer. Many external factors influence this; i.e., changes to government policies on infrastructure development and other economic issues can impact on construction demand, which may make job insecurity a constant issue in construction.

3. Research method

Figure 1 illustrates the methods deployed in this empirical research, which utilised a large database of construction accidents for developing the causation model. Accident data for the research were obtained from Safe Work South Australia, which is a state government agency responsible for work health and safety. They maintain a database of workplace accidents across all industries in South Australia. The database encompassed 29,205 construction accidents, reported during 2002-13. Filtering the database, a subset of 444 records was extracted, which described incidents related to psychological injuries to construction workers.

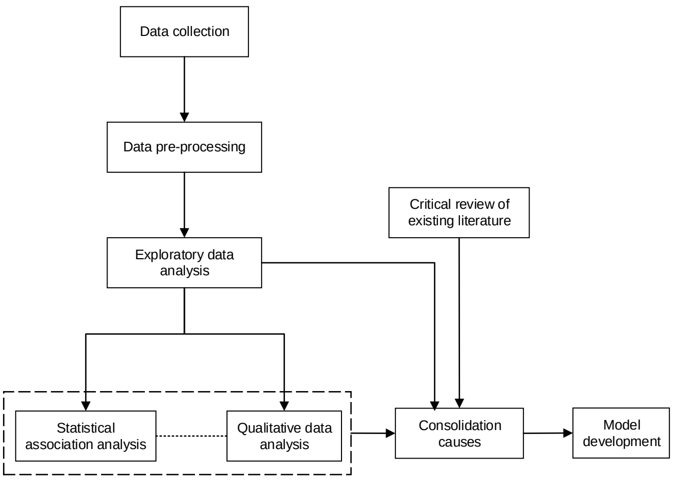

Figure 1: Research process and method

Pre-processing was undertaken to prepare the filtered data for statistical analysis. A typical case was characterised by variables such as: mechanism of incident, occupation, age, gender, language, nationality origin, experience, timing of incident, date of incident, employer size, description of incident, lost days and worker’s compensation paid. First, records that are not related to construction, but had been incorrectly recorded were removed (21 cases). Further checking was conducted to identify cases that are not significant for analysis. Forty-seven cases with both zero lost days and zero compensation were identified and removed, resulting in 376 usable cases for further analysis. Then, entries and descriptions across records were made consistent. Finally, nominal scales were introduced for variables that had numerical entries to facilitate non-parametric statistical analyses.

After the data pre-processing, an exploratory analysis using descriptive statistics was performed to gain a broader understanding of the psychological injuries in the South Australian construction industry. Subsequently, associations between the independent variables and the severity of psychological injuries were investigated using chi-square tests. While chi-square statistics are helpful for revealing associations they cannot be interpreted as causations. Thus, incident descriptions were qualitatively analysed to corroborate how the associations exhibit causation. Finally, findings from the quantitative and qualitative analyses and the literature review were consolidated, enabling the development of a new causation model for psychological injuries in the construction industry.

4. Quantitative data analysis and findings

The data set was redefined by 10 independent variables and one dependent variable (severity of psychological injury) in the pre-processing stage. In the original database, some of these variables were defined by different measurement scales, such as: occupation of victim had 67 job titles; age was in years; language background had 7 entries; nationality origin consisted of 9 countries; time of incident was 30-minute class intervals; and month of incident had 12 entries. Table 1 shows how these variables were re-categorised using nominal scales. Some of the categories, such as gender, mechanism of injury and employer size, were directly taken from the original dataset.

Table 1: Variable measurements

Variable	Measurement (nominal)
Independent variables:	
1. Mechanism of injury	Assault; exposure to a traumatic event; exposure to workplace or occupational violence; work pressure; workplace harassment and/or bullying; suicide or attempted suicide; other mental stress factor
2. Season of injury	Summer (Dec, Jan & Feb.); autumn (Mar, Apr & May); winter (Jun, Jul & Aug); spring (Sep, Oct & Nov)
3. Work shift of injury	Morning shift; afternoon shift; evening shift; night shift
4. Age range of victim	Under 20; 20 to 29; 30 to 39; 40 to 49; 50 to 59; over 60
5. Gender of victim	Male; female
6. Occupation category of victim	Office staff; site staff; trades personnel; machinery operator; apprentice; general worker
7. Experience of victim	Experienced worker; new worker
8. Native language of victim	English; non-English
9. Nationality origin of victim	Australian; non-Australian
10. Employer size	Small (1 to 20 employees); medium (21 to 200 employees); large (more than 200 employees)
Dependent variable:	
11. Severity of psychological injury	Minor; moderate; major; severe; critical

The dependent variable, severity of psychological injury, was derived based on the number of lost days reported for the cases. The utilisation of lost days to categorise injuries in to different severity levels has commonly been used by previous researchers who investigated physical injuries in construction; for example, Dumrak et al. (2013) and Arquillos et al. (2012). Nonetheless, varied severity levels and groupings of lost days were implemented by different researchers. This research adopted five levels of severity such as: minor, moderate, major, sever and critical, and the definitions for these categories are given below, which were derived from the risk matrix recommended by the National Patient Safety Agency (NPSA) (2008):

- **Minor** – psychological injuries requiring time off work (lost days) for shorter than 3 days.
- **Moderate** – psychological injuries requiring time off work (lost days) for 4 to 14 days.
- **Major** – psychological injuries requiring time off work (lost days) for 15 to 99 days.
- **Severe** – psychological injuries requiring time off work (lost days) for 100 to 365 days.
- **Critical** – psychological injuries requiring time off work (lost days) for longer than 365 days.

In interpreting the results, findings of both exploratory and chi-square analyses were looked at in a combined manner. The below sections expound the findings. In general, an upward trend in psychological injuries to construction workers in the South Australia is discernible. Whilst the severity level of psychological injuries are more on the minor category, the combination of major, severe and critical injuries constitutes one-third of all incidents. Given the psychological injuries are on constant increase, the ratio is likely to result in negative social outcomes and sufferings. It is therefore crucial that lessons are learnt from past incidents and measures are put in place to curtail them in the future. Table 2 elucidates chi-square analysis results. Interpretations of these results are provided below under appropriate subheadings.

Table 2: psychological injury severity pattern

Factor		Category (% of total accident)	% of accident within severity level				
			Minor	Moderate	Major	Severe	Critical
work-related factors	**Mechanism of psychological injury (x2 = 50.909, df =24, p =0.001)**	Being assaulted by a person or persons (12%)	80	2.2	0	13.3	4.4
		Exposure to a traumatic event (12.5%)	83	4.3	6.4	0	6.4
		Exposure to workplace or occupational violence (8%)	70	3.3	6.7	10	10
		Work pressure (33.2%)	54.4	2.4	23.2	17.6	2.4
		Work related harassment and/or workplace bullying (27.9%)	51.4	2.9	16.2	16.2	13.3
		Suicide or attempted suicide (0.8%)	100	0	0	0	0
		Other mental stress factors (5.6%)	76.2	4.8	4.8	9.5	4.8
	Occupation (x2 = 28.047, df =20, p =0.108)	Apprentice (6.6%)	72	4	4	8	12
		General worker (7.7%)	62.1	0	20.7	6.9	10.3
		Machinery operator (17.3%)	60	6.2	16.9	6.2	10.8
		Office staff (19.4%)	54.8	1.4	15.1	24.7	4.1
		Site staff (11.7%)	54.5	4.5	15.9	15.9	9.1
		Trade personnel (37.2%)	70	2.1	11.4	12.1	4.3
	Work shift (x2 = 13.257, df =12, p =0.351)	Morning shift (32.4%)	66.4	3.3	16.4	8.2	5.7
		Afternoon shift (21.5%)	63	3.7	7.4	17.3	8.6
		Evening shift (2.7%)	40	10	30	10	10
		Night shift (43.4%)	62	1.8	14.1	15.3	6.7
	Employer size (x2 = 29.209, df =12, p =0.004)	Large (34%)	56.3	5.5	24.2	9.4	4.7
		Medium (36.7%)	62.3	0.7	10.1	18.1	8.7
		Small (29%)	71.6	2.8	6.4	11.9	7.3
		Unknown (0.3%)	100	0	0	0	0
	Season (x2 = 27.245, df =12, p =0.007)	Autumn (24.5%)	66.3	0.0	15.2	9.8	8.7
		Spring (25.3%)	60.0	5.3	10.5	22.1	2.1
		Summer (22.9%)	73.3	2.3	8.1	10.5	5.8
		Winter (27.4%)	54.3	3.9	20.4	10.7	10.7
Worker-related factors	**Gender (x2 = 8.890, df =4, p =0.064)**	Female (19.1%)	50.0	2.8	18.1	22.2	6.9
		Male (80.9%)	66.1	3.0	12.8	11.2	6.9
	Age (x2 = 15.266, df =20, p =0.761)	Under 20 (1.9%)	71.4	0	28.6	0	0
		20 to 29 (14.9%)	69.6	1.8	10.7	12.5	5.4

4.1 Mechanism of incident

Data analysis revealed that work pressure and workplace harassment and bullying are the major causes of psychological injuries among construction workers with almost one-third of incidents are attributable to each. Moreover, these mechanisms are represented heavily in the major, sever and critical categories of injury severity. That is, work pressure recorded a total of 43.20% incidents in these categories whilst workplace harassment and bullying represented a total of 45.7%. Chi-square test results (x^2 = 50.909, df =24, p =0.001) reveal that there is a statistically significant association between injury severity levels and incident mechanisms.

4.2 Occupation

In terms of occupation, trades personnel were heavily represented in psychological incidents, followed by office-based employees of construction organisations and then machinery operators. Even though no statistically significant association between the occupations and the psychological injury severity levels was observed (x^2 = 28.047, df =20, p = 0.108), a quarter of office-based employees in construction suffered severe injuries, which resulted in time-off-work between 100 days and a year.

4.3 Work shift

No statistically significant association was observed between work shifts and psychological injury severities (x^2 = 13.257, df =12, p = 0.351). This finding contradicts with literature on severities in physical injuries, which confirms that a large proportion of fatalities occur in afternoon shifts (known as 'after lunch effect'), and more injuries occur in morning shifts. However, night shift workers represent psychological injury statistics heavily, across severity categories of major, sever or critical.

4.4 Worker's gender

Females accounts for only 13% of the South Australian construction workforce (Australian Bureau of Statistics 2013); but, they are represented doubled the rate for male workers in severe psychological injuries, as revealed in this study. In other categories of severities, females and males seem to represent almost similarly, leading to weak chi-square statistics (x^2 = 8.890, df = 4, p = 0.064) to conclude that there is no significant association between gender and psychological injury severity.

4.5 Worker's age

Past studies on physical injuries have concluded that the severity of physical injury increases with the age of workers (Arquillos et al. 2012). However, this study has found that there is no significant association between the age and the severity of psychological injury (x^2 =15.266, df =20, p =0.761). Age groups such as 30 - 39, 40 - 49 and 50 - 59 are nearly equally represented in the overall records.

4.6 Worker's experience

This study indicated a weak association between experience and psychological injury severity (x^2 =9.949, df =4, p =0.041). In contrary to psychical injuries reported in literature, new workers represented double the rate of experienced workers in the severity category of 'critical' psychological injuries that lead to time-off-work for longer than a year.

4.7 Worker's nationality origin and native language

Australian-born workers represented more in psychological injury statistics than overseas-born workers and an association is noted between the nationality origin and the injury severity (x^2 =18.553, df =8, p =0.017). However, language background of the worker did not show any association. Australian workforce comprises 26% persons born overseas (Australian Bureau of Statistics 2010), but their representation in psychological injury statistics (13.6%) is lesser. Nevertheless, they are disproportionately represented (37.2%) in injury categories of major, severe and critical.

4.8 Employer size

Only minor differences in the number of psychological incidents was observed across employer sizes though a significant association between the employer size and injury severity levels was apparent (x^2 =29.209, df =12, p=0.004). Small organisations represent more in minor incidents whilst nearly 25% of incidents occurred in medium-sized organisations resulted in severe or critical injury outcomes. A similar proportion of incidents in large organisations caused major psychological injuries. No significant differences in the percentage of critical incidents arose in small and medium organisations.

4.9 Season

The climatic season of winter recorded slightly a higher number of incidents (27.4%) of psychological injuries than spring (25.3%) and autumn (24.5%). Similarly, winter accounted for the largest proportion of major, sever and critical incidents than the other seasons, with a total of 41.8% of all the incidents occurred in that season. Chi-square test results also prove that there is a strong association between the season and injury severity (x^2 =27.245, df =12, p =.0007).

5. Qualitative data analysis and findings

The quantitative analysis displayed the aforementioned patterns within the incident cases. However, they did not explain the underlying issues that yield them. Hence, the qualitative analysis probed into the incident descriptions reported by victims and the following trends were discovered.

- One of the major causes of work pressure was excessive workload along with working long hours, sometimes continuously working without breaks, and trying to achieve unrealistic goals set by the management. Most of the workers were unable to cope with such excessive workloads, found the job to be very stressful and ended up having anxiety and depression. As reported by one of the victims "I was standing in the yard, shaking in tears, unable to achieve..... build up of pressure due to worrying about getting the job done on time........ unbearable work load".
- Under workplace harassment, bullying was reported to be the major issue followed by verbal abuse and sexual harassment. Interestingly these were mainly committed by co-workers rather than the management or employer. In most cases victims reported an ongoing harassment for a long time; for example, a worker indicated "I was going about my normal duties and could no longer handle the harassment and bullying that I was suffering. I find harassment about on that I had nothing to do with". Few cases of threatening behaviours either by a co-worker or employer were also reported. For example, a worker reported "I was victimised by the directors of the company and made to feel threatened and bullied. I feared for my life and felt

very unsafe at work. I had to call the police" and another worker alleged "I received threatening phone calls at night. Caller said he would kill or damage me and my family".

- Few workers reported stress and anxiety due to repetitive tasks over a long period of time. Others reported work environment to be the major cause of work pressure. They have experienced intolerable conditions and unsafe work practices that led to work stress.
- Confrontations with the employer or management were reported as causes of work stress. Arguments, aggressive and violent actions at meetings, false accusations, allegations of misconduct were the major reasons behind these confrontations.
- Job uncertainty, non-payment, underpayment or delayed payments of wages were also found to have caused depression. In few cases, unfair dismissals have caused stress.
- Work situation (isolation) and workload were cited as main reasons for anxiety and depression that led to very long absenteeism.

The qualitative analysis was extended to scrutinise the level of injury severity against incident descriptions and discovered the below patterns in the incident cases.

- Critical incidents were predominantly caused by multiple sources of harassment over a period; for example, "work and work environment causing anxiety, panic attacks and depression due to harassment, bullying and victimization"; and "workplace bullying, verbal and behavioural threats, sexual harassment, undermining authority, defamation".
- Unlike the above, severe incidents were equally caused by harassment and work pressure. Seventy-five percent of major incidents were caused by work pressure while only 25% were due to harassment; for example, a worker reported "work related stress and anxiety due to staff shortages and performing work of two", and another worker's account "work pressure, working long hours, work overload, and overseeing too many projects".

6. Discussion

The empirical analysis investigated the influence of personal factors (age, gender, experience, nationality and language background), work factors (occupation, work shift, work conditions, and employer) and environmental factors (season) on the psychological injury outcomes in the construction industry. It has been found that work factors have predominant influence in psychological injuries than other factors. Hence, the seven themes discovered in the literature research are confirmed to be relevant to the construction industry. However, the degree of influence varies in the construction industry setting in the descending order of: (1) workplace harassment and bullying, (2) work pressure, (3) work-life conflict, (4) discrimination, (5) poor physical work environment, (6) job uncertainty, and (7) poor workplace relationships. Similarly, the above order is also a reflection of the severity of these incidents, where harassment and bullying resulting mainly in critical to severe outcomes while work pressure and work-life conflict lead to severe to major outcomes. Other causes are not generally associated with higher order severities. It is interesting to observe that all critical incidents, except four cases, were caused by harassment and bullying. Thus, the study clearly highlights the need for curbing harassments and bullying to make construction workplaces free from critical psychological incidents.

7. Formulation of a causation model for psychological injuries

The findings of the two distinct research methods were consolidated and corroborated towards formulating a causation model for psychological injuries in the construction industry. Figure 2 demonstrates the model by mapping out the factors and their influence paths. The far left end of the diagram encompasses seven umbrella stressors with their originating sources. Being a victim of one or a combination of these stressors causes emotional distress with feelings such as tension, anxiety, insecurity, frustration and/or trauma in workers. Enduring these distress symptoms for an extended period can lead to excessive mental stress. When the excessive stress is not controlled, it can result in psychological depression, which often impacts on the physical health, behavioural and social patterns/habits, work performance and family relationships. These negative consequences in turn reinforce the emotional distress and mental stress.

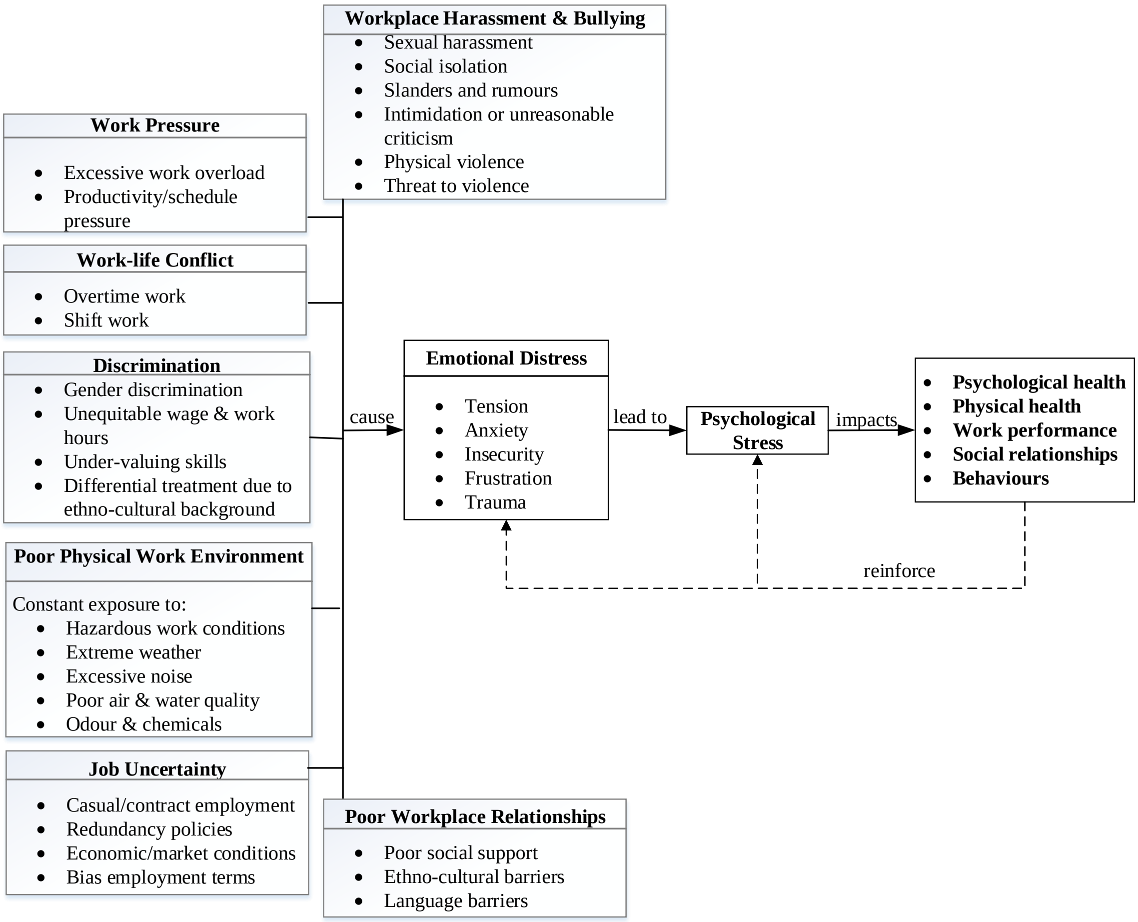

Figure 2: Causation model for psychological injuries

8. Conclusion

While numerous models have been developed by researcher to explain the causation of workplace accidents and health damages that occur to construction workers, silently suffered psychological injuries have not gained attention. This study proposes a causation model, which maps out seven factors along a stress influence path. The factors include: workplace harassment and bullying, work pressure, work-life conflict, discrimination, poor physical work environment, job uncertainty, and poor workplace relationships. The degree of distress exerted by workplace harassment and bullying, and work pressure is found to be more significant in the construction industry context than that of caused by other stressors. Workplace harassment and bullying have the potential to cause psychological damages that can lead to lost days in excess of a year and excessive work pressure could result in lost days due to psychological injuries longer than 100 days. Hence, these factors warrant special attention and scrutiny from organisational management as well as WHS authorities in order to maintain a construction industry that is free from serious or critical psychological incidents.

Global Real Estate Sustainability Benchmark (GRESB Survey): Improving Sustainability Performance in the Commercial Real Estate Sector in the Nordics

Anne Kaiser

Ramboll Finland Oy, Finland
Email: anne.kaiser@ramboll.fi

Abstract

Considering the globe and the built environment, commercial real estate sector is one of the largest consumers of natural resources and greatest polluter with reference to GHG emissions and solid waste production. Among initiatives to reduce environmental impact of commercial real estate industry, Global Real Estate Sustainability Benchmark or as since December 2015 GRESB Real Estate Assessment (GRESB Survey) focuses on collecting information regarding sustainability performance of property companies and funds.

The purpose of this paper is to analyse GRESB Survey as a tool to improve the sustainability performance of commercial real estate industry. Drivers to participate, benefits, best practices and challenges with GRESB Survey among Nordic real estate companies and funds were analysed in the recent research conducted by the author.

This research on GRESB Survey and commercial real estate sustainability is a practical investigative research conducted during October 2014 – April 2015. Research data was collected by interviews and web surveys. Interviews and web survey addressed four different target groups; real estate investment companies and funds, real estate user owners, GRESB investor members and institutional investors aligned with principles of responsible investment.

Benchmark data with peer organizations provided by GRESB Survey directs participants' sustainability efforts, helps in allocation of resources, brings sustainability on the top management agenda and connects companies with investors on sustainability issues. GRESB Survey participation requires dedication, time, resources and willingness to meet challenges. GRESB Survey develops in agile way and it is expected to "raise the bar" over the years and become more analytical and detailed. Together with development of GRESB Survey itself and growing number of users, also other actors within real estate industry are developing new services and aligning existing services to better support real estate companies and funds with sustainability performance improvement through the GRESB Survey.

Keywords: Sustainability, ESG, GRESB Survey, GRESB Assessment, sustainability services

1. Introduction

Sustainable development is about integrating the needs of society while maintaining earth's ecological capacity and not endangering the possibility of future generations to meet their needs. Three dimensions of sustainable development; economical, environmental and social dimension, are interdependent and mutually reinforcing.[1] Built environment and buildings are responsible annually on global level for more than 40% of energy consumption, 30% of energy-related greenhouse gases (GHG) emissions and considering the whole building sector 30% of resource consumption, 12% of fresh-water use and 40% of total solid waste generation. On average building sector employs more than 10 % of global workforce. Construction and real estate sector play a significant role in the response to climate change and have substantial potential for sustainable reduction of emissions with minimum investments or even with net savings.[2] Considering the globe and the built environment, commercial real estate sector is one of the largest consumers of natural resources and greatest polluter with reference to GHG emissions and solid waste production.[3]

Along growing global awareness of the environmental impact of buildings and commercial real estate, sustainability has gained more important role in the real estate sector with environmental sustainability focus. However, the adaptation of sustainable principles has been hindered by the lack of evidence of concrete financial benefits and common agreements how to share the cost burden and benefits between investors, owners, fund managers and tenants regarding investments improving sustainability in real estate sector.[4]

Among initiatives to reduce environmental impact of commercial real estate industry, GRESB Survey focuses on collecting information regarding sustainability performance of property companies and funds. Benchmark information serves institutional investors and participants themselves to monitor, benchmark and improve sustainability performance further. GRESB Survey is aligned with international sustainability reporting schemes as Global Reporting Initiative G4 (GRI G4), UN Principles for responsible investment (PRI), Dow Jones Sustainability Index (DJSI) and Carbon Disclosure Project (CDP). GRESB Survey is not limited on environmental aspects only while it covers broader sustainability issues in terms of ESG criteria, such as sustainability management, assessment of sustainability risks, sustainability improvement programs and stakeholder engagement.[5]

GRESB Survey participation requires dedication, time, resources and willingness to meet challenges. GRESB Survey develops in agile way and it is expected to "raise the bar" over the years and become more analytical and detailed. Together with development of GRESB Survey

itself and growing number of users, also other actors within real estate industry are developing new services and aligning existing services to better support real estate companies and funds with sustainability performance improvement through the GRESB Survey. The purpose of this paper is to analyse GRESB Survey as a tool to improve the sustainability performance of commercial real estate industry and to discuss the range of services Ramboll can provide to real estate companies and funds to support both GRESB Survey participation and consequent development processes to improve sustainability performance further.

Two following chapters describe GRESB Survey and applied research methodology. The chapter four focuses on benefits and challenges related to GRESB Survey as well as on identified best practices and GRESB Survey's potential to improve sustainability performance of real estate investment funds and companies. Furthermore available tools and external services supporting GRESB Survey participation are discussed. Last chapters focus on business opportunities around GRESB Survey and its significance to different actors among commercial real estate industry.

2. About GRESB Survey

GRESB –survey was started in 2009 through a survey project of Maastricht University aiming to develop "Environmental real estate index". In five years GRESB Survey has developed into a global standard to assess the sustainability of real estate portfolios.

GRESB Survey contains 42 basic questions and 14 questions covering new construction and major renovation activities. The survey collects information on performance data as energy, GHG emissions, water and waste. In addition GRESB Survey covers also sustainability risk assessment, performance improvement programs and engagement with employees, tenants, suppliers and community. Reported sustainability aspects are divided into following sections:

- Management e.g. strategy, objectives, resources, decision-making.
- Policy and disclosure e.g. guidelines, policies, reporting and third party reviews.
- Risks and opportunities e.g. governance and sustainability.
- Monitoring and environmental management systems and certifications.
- Performance indicators e.g. energy, GHG and water data, waste management.
- Building certifications e.g. green building certificates and energy ratings.
- Stakeholder engagement e.g. employees, tenants, suppliers and local communities.
- New construction and major renovations:
    - Sustainability requirements of projects and sites
    - Community engagement and socio-economic impact
    - Materials and certifications
    - Energy efficiency
    - Requirements for occupant wellbeing, energy and water efficiency
    - Supply chain requirements
    - Health and safety on-site

GRESB allocates an overall GRESB score to each participating real estate company or fund. Due to complexity of the sustainability and real estate sector as well as variations between countries and regulatory environments, companies and funds are analysed through peer group benchmark instead of absolute sustainability performance. Peer group comparison takes into account country, regional, sector and investment type of variations.

Participation to GRESB Survey is free of charge. GRESB on-line survey reporting period is between 1st of April and 1st of July. Survey submissions are validated during the months of July and August. GRESB Survey results are published in September. Participants receive their GRESB Scorecard with headline results as overall score, strengths and weaknesses and the score on reported sustainability aspects. For extra charge, survey participants can purchase complete and more detailed benchmark report covering single answers of the GRESB Survey. Key figures describing the scope of GRESB Survey are illustrated in the table below.

Table 1: GRESB Survey highlights 2014-2015.

	2014	*2015*
GRESB participants	*637*	*707*
GRESB investor members	*46*	*51*
Company and fund manager members	*56*	*87*
Associate members	*21*	*28*
Partners	*12*	*13*
Institutional capital	*$5.5 trillion*	*$6.1 trillion*
Property value	*$2.1 trillion*	*$2.3 trillion*
Assets covered	*56000*	*61000*
New construction and major renovation assets	*3329*	*4127*

3. Research methodology

This research on GRESB Survey 2014 and commercial real estate sustainability is an investigative field study. Collection of research data was conducted between October 2014 and March 2015. Data was collected by interviews and with web-surveys. Nine interviews were conducted in November 2014 with a sustainable investment consultant and five real estate companies and funds in Finland and in Sweden.

Web-surveys were conducted with Webropol on-line survey and analysis software. Altogether four web-surveys were conducted for different commercial real estate actors. Web-surveys for real estate companies, funds and user-owners were conducted between December 2014 and March 2015. Target group was divided in two groups; companies already participating into GRESB Survey (GRESB - pioneers) and companies potentially interested in participation into GRESB Survey (GRESB - potentials). Web-surveys for investors were conducted between January and March 2015. Also investor target group was divided into two; GRESB investor members (GRESB – investors) and investors not being members of GRESB (Non-GRESB-investors).

Web-surveys included both multiple choice and open-ended questions. Survey was sent as an email link to targeted respondents and survey was also promoted in social media, LinkedIn. The survey had total 41 respondents (including the interviews) and the distribution of respondents is illustrated in following table. Sample size is approximate due the promotion of the survey in social media, but illustrates the number of emails sent to target groups with the survey link. Web survey participation was voluntary and respondents could skip any question and discontinue at any point. All responses are anonymous and kept confidential.

Table 2: GRESB Survey –research sample sizes and response rate.

Target group	*Responses*	*Sample size*	*Response rate*
GRESB – pioneers	*14*	*15*	*93 %*
GRESB – potentials	*17*	*70*	*24 %*
GRESB – investors	*7*	*33*	*21 %*
Non–GRESB-investors	*3*	*50*	*6%*
TOTAL	*41*	*168*	*24 %*

At the time of the research a total of 15 real estate investment companies and funds were identified as GRESB Survey participants in the Nordics. Later it was revealed that altogether 21 real estate companies and funds in the Nordics participated into GRESB Survey in 2014 and the number of participants grew into 41 participants in GRESB Survey 2015.[6]

The aim of the research was to understand:

- Benefits of GRESB Survey?
- Best practices and challenges with GRESB Survey?
- If GRESB Survey does help companies and investors to improve the overall sustainability performance? And how eventually?
- On what matters are external partners used in sustainability reporting process and GRESB Survey participation?
- What kind of tools, programs and software is used to facilitate data collection in connection to sustainability performance indicators?

[6] 2015 GRESB Report – Europe Snapshot, p.1.

4. Impressions about GRESB Survey

Real estate companies and funds, especially listed ones, are faced by the burden of ”multiple sustainability reporting”. Some of the sustainability reporting frameworks such as GRI, CDP, DJSI and EPRA are well established and ”institutionalized” among commercial real estate companies and funds in their efforts to communicate to their owners, investors, creditors and other stakeholders about their sustainability efforts and commitment. What are the perceptions towards GRESB Survey, an additional sustainability reporting framework among many others?

Real estate companies and funds participating into GRESB Survey consider it the most important sustainability reporting scheme backed by GRI sustainability reporting. GRESB Survey is seen to have focus on industry-related, material aspects and as a valuable tool for improving the sustainability performance of real estate companies, funds and commercial real estate portfolios. Benchmark data with peer organizations directs sustainability efforts, helps in allocation of resources, brings sustainability on the top management agenda and connects companies with investors on sustainability issues. It should not be seen as “judgement” of existing practices, but as a starting point of a continuous improvement process.

4.1 Benefits of GRESB Survey

While asking the importance of different sustainability reporting and assessment schemes, there is no doubt of how strong position GRESB Survey has when compared with sustainability reporting frameworks as illustrated in Figure 1. GRESB pioneers as reporting companies consider also the importance of other schemes as GRI reporting and EPRA Sustainability BPR. Sustainability reporting according GRI guidelines is considered by one interviewee as something that “Once you start, you can’t give it up...” It is very improbable that GRESB – survey would replace GRI sustainability reporting as GRI serves all stakeholder groups and is an “open access system” once published on-line.

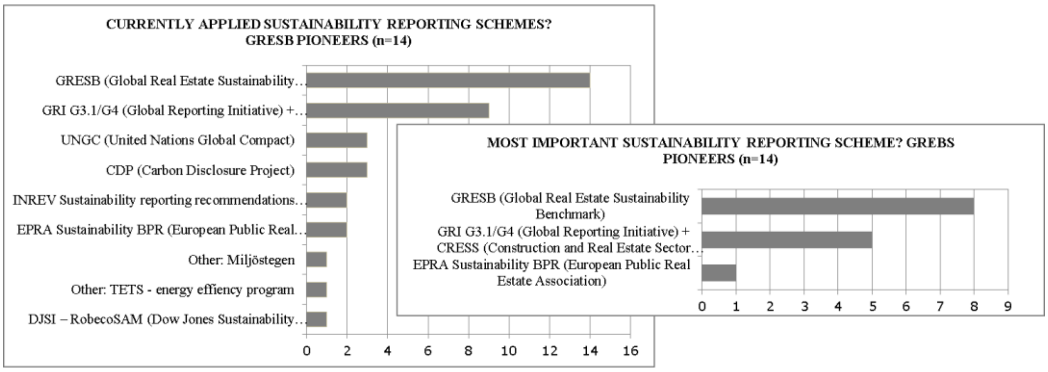

Figure 1: Sustainability assessment schemes used by GRESB pioneers.

According to GRESB – potentials open-ended responses, sustainability reporting pushes companies to set indicators in the first hand. Monitoring and reporting on environmental e.g. energy indicators leads to setting more precise targets for improvement and follow-up of the performance. Setting up reasonable targets enables reaching them with natural consequence of positive results that motivates companies to set more challenging targets, widening the scope of environmental targets or investing in sustainability efforts.

Figure 2 illustrates benefits GRESB Survey provides both for GRESB – investors and GRESB – pioneers. Among benefits provided by GRESB Survey, the GRESB – investors emphasized increased transparency towards investors themselves as the key benefit provided by GRESB Survey. According to open-ended answers GRESB Survey gives investors pieces of information they have not thought about before and this information can be used as a catalyst for new sustainability initiatives. One respondent highlights the idea of implementing a "robust" Green Lease as new standard for all office and retail asset. When not all companies and funds within the investment portfolio are participating into GRESB Survey, investors tend to engage with them with issues and ideas from GRESB Survey, resulting in improvement the overall sustainability performance of the portfolio.

Communication and branding benefits as well as improved credibility of sustainability disclosure rank high among benefits of GRESB – pioneers. Furthermore the survey gives new ideas from peer group and from the survey itself. GRESB Survey directs sustainability efforts by evidencing aspects that may not be considered earlier and showing where the industry is heading to regarding sustainability. Several interviewees see GRESB Survey as a development tool for sustainability, showing what is material and important in the real estate industry. GRESB Survey encourages self-evaluation which leads to self-reflection and works as natural, in-born catalyst for sustainability improvements.

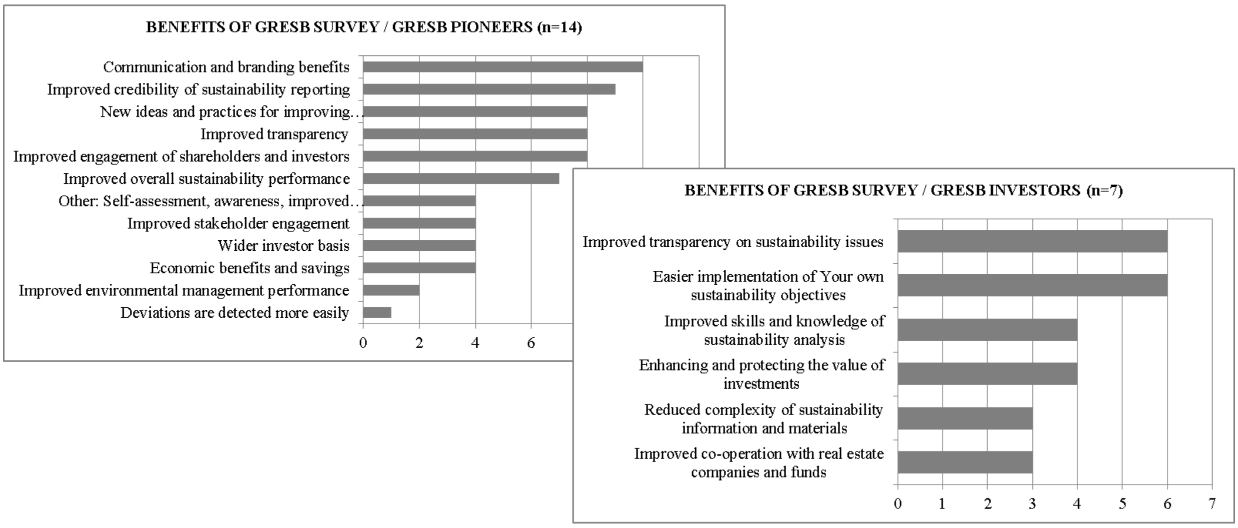

Figure2: Benefits provided by GRESB Survey.

One interviewee emphasizes the global focus and approach to sustainability innovations of GRESB Survey as feeding the real estate industry over the time with new ideas as innovations become everyday work and are found as a part of the GRESB Survey questions.

After completing GRESB Survey, as revealed by open-ended responses participants got to know what they have to actually work with e.g. focus more on water consumption of to develop external communication about sustainability on their website. GRESB Survey reveals strengths and weaknesses of companies and helps to prioritize and allocate resources correctly in actual and relevant sustainability aspects.

Improved transparency and connectivity with investors is naturally important for GRESB – pioneers. Furthermore GRESB Survey is described in open-ended responses of GRESB - pioneers also as a tool for putting sustainability on the agenda of top management in concrete and appetizing way. First it pushes for more structured management of sustainability aspects and making sustainability more concrete and simpler to deal with. Second as a consequence, GRESB Survey facilitates target setting, measurement and communication about sustainability efforts with management, investors and own personnel. As one interviewee describes: "GRESB Survey visualizes connection between sustainability work and progress to all employees. It gives a new meaning to sustainability work."

4.2 Challenges and best practices with GRESB Survey participation

Challenges experienced with GRESB Survey participation are dependent on knowledge and experience of sustainability reporting and sustainability data collection practices of participating organizations. Many of private real estate investment companies and funds are small and medium sized companies (SME), often with less than 30 employees. Private SMEs have also different governance and reporting obligations as listed, public real estate investment companies and funds.

Data collection and processing existing data into GRESB Survey –format, where the aim is to collect data by property types and separate consumption and waste data between landlord and tenants. When portfolio includes many multi-purpose properties, division of energy consumption data between different property types leads to excessive manual calculation and aggregation of performance indicators. Generally the amount of data; performance indicators, process descriptions and evidencing documents may be challenging for SMEs and portfolios with large number of properties.

Survey is perceived as rigid and data to be submitted must be very precise. As GRESB Survey has global reach and it develops over the time, some questions remain generic, difficult to understand and without common clarification.

Respondents were asked to share best practices applied in connection of GRESB Survey participation. First timers should consider GRESB Survey as a starting point in a process of continuous improvement, not as judgement of existing policies and performance. When there is no clarification for a problem participant is dealing with, it is important to make own conclusions and assumptions, explain them thoroughly and be consistent with methodology over the time. Time and resources can be saved by getting familiarized with GRESB Survey guidance, committing top management and other people and functions needed in reporting process properly and well in advance. Sharing and publishing information about sustainability commitment, efforts and activities facilitates GRESB Survey submission. One respondent describes: “Don’t overdo. Use what you have and build on that.”

4.3 Does GRESB Survey help to improve sustainability performance?

One central question of this survey is, whether GRESB Survey actually helps companies to improve sustainability performance. To start the analysis it is feasible first to understand what kind of benefits improved sustainability performance may offer to real estate companies and funds according all respondent groups. Improved sustainability is first associated with reduced operating costs and environmental impact of properties. Secondly it is associated with health, comfort and higher quality of buildings, which consequently may result in improved tenant satisfaction and commitment. Furthermore branding, marketing and sales related benefits are emphasized together with meeting investors’ and shareholders’ sustainability criteria (Figure 3).

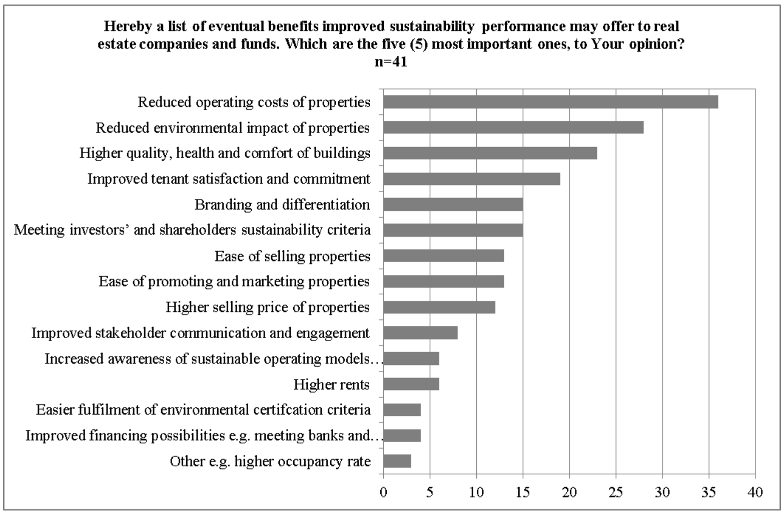

Figure 3: Benefits of improved sustainability performance.

Both GRESB – pioneers and GRESB – investors were asked whether GRESB Survey helps to improve overall sustainability performance, on company or on the real estate investment portfolio level. All except one of GRESB – investors witnesses GRESB Survey role in this improvement process Within GRESB – pioneers majority sees GRESB Survey as a tool for improving overall sustainability performance, but the difference is not so clear (Figure 4).

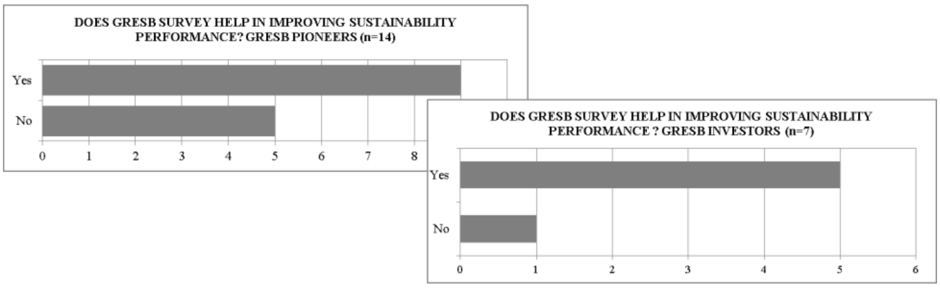

Figure4: Does GRESB Survey help in improving sustainability performance?

Still interviews and open ended comments emphasize clearly the practicality, benchmarking function and real estate industry focus of GRESB Survey in improving sustainability performance of companies and funds.

4.4 GRESB Survey and external partners, tools, programs and software

External partners are used in connection to sustainability reporting and GRESB Survey by two thirds of respondents in both GRESB pioneers and GRESB potential group. One group of external partners are marketing and communication agencies providing services for design, repro, printing and composing texts. Consumption data collection, calculation of emissions and environmental performance indicators as well validation of data to be reported is other group of tasks that are commonly outsourced to external partners. As already mentioned GRESB Survey indicators require asset level data, division between landlord and tenant as well as aggregation of data by property types, which may make the GRESB Survey more challenging in comparison to GRI sustainability reporting.

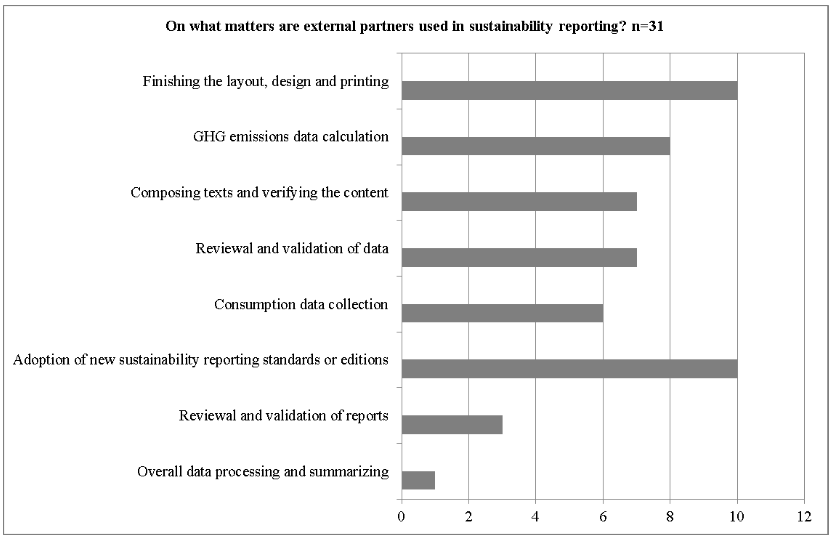

Figure5: Does GRESB Survey help in improving sustainability performance?

According to the open-ended responses, almost half of the respondents both in GRESB – pioneers and GRESB – potential groups use a variety of tools, programs and software to facilitate sustainability reporting and actual sustainability performance at the end. Data management systems are getting more sophisticated and more commonly used by real estate companies. Furthermore data management systems are also adapted to meet the criteria and requirements of different sustainability reporting frameworks. Good example of this is Nuuka Solutions's DMS elaborating data into GRESB Survey format, developed together with Genesta Property Nordic AB. This is a good example how sustainable innovations and practices are spread and shared for the benefit of whole industry and society.

Respondents use both internally and externally developed software and tools for data collection, monitoring and reporting. In some cases existing applications as electronic maintenance manual is customized and developed further to provide information for sustainability monitoring and reporting. In some cases the overall responsibility on data collection, monitoring and reporting is given to service providers. Most commonly used external tools are: Vitec Energy / WebEss, Credit 360°, Nuuka DMS and RESPECT Europe Svante. Widening the focus from energy, water, waste and GHG data collection and monitoring into overall sustainability data collection, some respondents view this comprehensively summing up different stakeholder, employee and customer satisfaction surveys with data management as well as financial reporting and consolidation tools.

5. Discussion

External partners as consultants should be recognizing the growing importance of GRESB Survey in improving the sustainability performance of real estate investment companies and funds. Sustainability communication and reporting is not requested only from listed, public real estate investment companies and funds, smaller organizations should follow and adopt new practices to meet growing demand for sustainability data by tenants, investors, financers and employees. Ramboll has recognized this opportunity and actively aligns existing services and develops new services to facilitate GRESB Survey participation to any size of real estate investment companies and funds. It is not only organizations participating into GRESB Survey, but also institutional investors and financing institutions which can be helped by Ramboll to develop further their sustainability assessment process of commercial real estate portfolios within the GRESB Survey framework.

Ramboll has gained a wide knowledge and experience around GRESB Survey and works actively with real estate companies and funds by providing various services to facilitate GRESB Survey participation of first timers and more experienced participants. Ramboll GRESB Survey services cover the whole GRESB Survey process from assessing the actual state of sustainability management, monitoring and reporting capabilities into analysing GRESB Benchmark Report with identification of respective short-, medium- and long-term development issues. Most successful project resulting in GRESB Green Star award and comprehensive development of sustainability performance has been carried out as in-house consulting.

6. Conclusions

GRESB Survey is considered very important sustainability ranking scheme by respondents, backed up by GRI reporting. GRESB Survey offers new ideas and insight both for the improvement of sustainability performance of real estate investment companies and funds as well for sustainability assessment process of institutional investors. GRESB Survey is material and practical framework which improves sustainability performance of real estate investment companies and funds and investor members’ commercial real estate portfolios.

Benchmark data with peer organizations directs sustainability efforts, helps in allocation of resources, brings sustainability on the top management agenda and connects companies with investors on sustainability issues.

GRESB – survey participation requires dedication, time, resources and willingness to meet challenges. Pioneering real estate consultants as Ramboll are aware of the growing role of sustainability in improving overall profitability of real estate investment companies and funds and securing long-term value of properties. GRESB Survey has proven to be a material, concrete tool in improving sustainability performance of commercial real estate industry by pushing participants to improve sustainability management and communication processes.

External partners as consultants have been recognizing the growing importance of GRESB Survey in improving the sustainability performance of real estate investment companies and funds. Wide range of skills and capabilities are developed to support listed, public real estate investment companies and funds, as well as private real estate investment companies and funds in their sustainability work to meet requirements of institutional investors covering commercial real estate investment universe. GRESB Survey will develop and "raise the bar" until sustainability will be managed with same regime and accuracy as company financials.

Abstract

The purpose of this study is to provide reliable service of materials information portal through the establishment of public big data by collecting and integrating scattered low energy building materials and equipment data. In the establishment of low energy building materials database in the country, there was almost no case of integrating scattered data based on the standardized data classification system and code. Therefore, data attribute items were extracted based on information highly used in the building market in this study in order to establish building materials database, and data standardization was carried out through the definition of attribute of such entities.

Keywords: Materials information portal, building materials database, entity definition, data standardization

1. Introduction

Price comparison web sites in Korea mainly target consumer goods used in everyday life such as clothing and home appliances, but a website providing real estate information has appeared recently so that the object of service is becoming more diversified. The service provided by those web sites is mostly price comparison, product and consumer review information, allowing users to obtain information regarding a desired product and product manufacturers to have price competitiveness. When consumers purchase a product, the product, product quality and diversity are emphasized for decision making, and they can receive information regarding the product promptly through a price comparison web site and purchase the same product at a low price. Due to such advantage, 51% of consumers who purchased a product actually purchased a product after price comparison through a price comparison web site, and 45.4% among them considered product reviews when deciding whether or not to purchase the product (Ma, Mi-Yeong (2008)). The Public Procurement Service, the central procurement agency of Korean government, opened Korea On-line E-procurement system in 2002 and currently 47,000 public agencies and 270,000 procurement companies use this system in all procurement stages including the registration of company, bidding, contract, inspection and payment (Public Procurement Service (2015-1)). Korea On-line E-procurement system plays a role of single window for public e-procurement by integrating bidding information of all public agencies, but since publicness of purchase should be considered in addition to economic rationality, so this system has the relevant limitation unlike private procurement. The purpose of this study is to establish low-energy building materials information database in order to provide low-energy building materials information portal service by applying the concept of price comparison web site explained above into building materials & equipment field.

The low energy building materials information portal (hereinafter referred to as 'materials information portal') in this study is established at national level with quasi-governmental agencies including Korea Energy Agency and Korea Appraisal Board, and as the concept of general-purpose service targeting whole nation, this portal integrates scattered database and provide reliable contents related to government systems and policies in order to allow portal service users to select a desired product rationally. Also, this portal leads healthy competitions between companies through the product price and quality comparison so that reasonable prices can be established in the market. Besides building materials and equipment data, for service provision, data related to laws, excellent cases of low energy buildings and economic evaluation should be added and supplemented to complete the integrated information database, and building materials database among the integrated information database includes core information for the whole construction tasks including design, construction, purchase and estimate. Therefore, efficient data collection, classification and continuous update regarding building materials are required, so the purpose of this study is to examine the establishment and expansion of materials database for establishing materials information portal.

2. Status of materials database establishment in Korea

2.1 Korea Prices information

Korea Price Information, Corp. is a price investigation and cost accounting service agency registered on the Ministry of Strategy and Finance and it has establish database by integrating price and survey information and provides information through Korean prices information sheet through on- and off-line. The price information shown in the prices information sheet can be used in studies and practical fields regarding the calculation of equipment cost and initial investment amount, and basic information such as the model name and specifications is uploaded by companies and the detailed information including product catalogue can be checked through the link of company's website. Information based on the unit price of product is provided except for construction or installation cost.

2.2 Efficiency management machinery, equipment or materials and high-efficiency energy machinery, equipment or materials

Korea Energy Agency operates the energy consumption efficiency rating indication system and high-efficiency energy using appliance certification system, and the energy consumption efficiency rating indication system is the obligatory report system to lead manufacturing companies that produce applicable products for energy consumption efficiency rating indication system to produce and sell energy-saving products (efficiency management machinery, equipment or materials) from the production step in order to allow consumers to check and purchase highly efficient energy-saving products easily. In this system, products are indicated separately into 5 grades according to energy consumption efficiency or energy usage, and the minimum energy efficiency applies to Minimum Energy Performance Standard (MEPS). Target items are 28 items including electric cooling apparatus and an energy consumption efficiency rating label cannot be attached to any product not announced in the Ministry of Trade, Industry and Energy's efficiency management machinery, equipment or materials operating procedure.

High-efficiency energy using appliance certification system is voluntary system to certificate a product of which energy efficiency and quality test results satisfies a certain standard announced by the government as high-efficiency energy machinery, equipment or materials. This certification system is to revitalize distribution of high-efficiency energy products and certificate is issued by Korea Energy Agency upon a voluntary request of manufacturing company. The target items are 47 items and any product not included in the application range announced in the Ministry of Trade, Industry and Energy's regulation on the distribution and promotion of high-efficiency energy machinery, equipment or materials is not subject to high-efficiency certification. The materials information database in this study is established with only items related to the building energy usage for two systems above. The characteristics of information included in the prices information sheet in Korea, efficiency management machinery, equipment or materials, and high-efficiency energy machinery, equipment or materials are as shown in Table 1 below and systematic construction of the materials information database is showed in Figure 1.

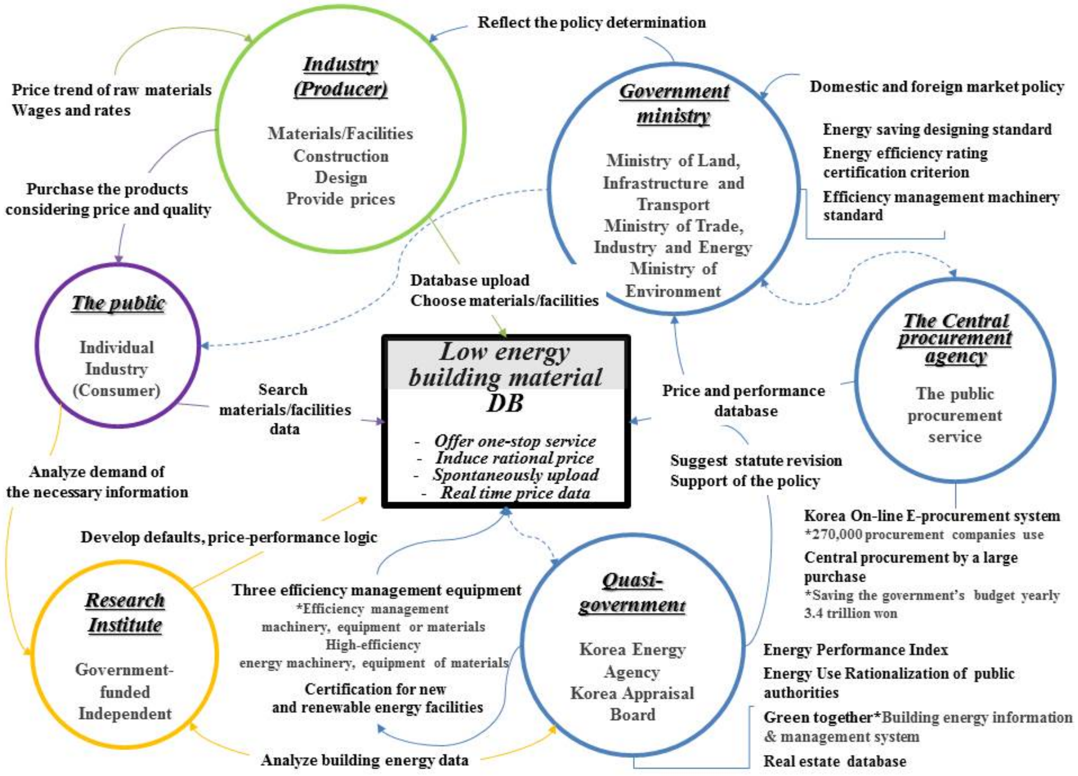

Figure 1: Systematic construction of the materials information database

Table 1: Properties of the materials database in Korea

Classification / source	*Characteristics of available information*	*Depth of information (eg: boiler)*
Public Procurement Service	*Building, machine & equipment, electricity, materials and construction cost* *(Based on price)*	*Boiler* *Model name, capacity, unit price*
Prices information sheet	*Price information such as building, facility, electricity, lighting and survey information, etc* *(Based on price)*	*Gas boiler* *Model name, company name, specification, unit price*
Efficiency management machinery, equipment or materials	*Applicable product for energy consumption efficiency rating indication system* *(Based on performance)*	*Gas boiler for home* *Model name, company name, heating thermal efficiency %, efficiency level*
High-efficiency energy machinery, equipment or materials	*Applicable product for high-efficiency test* *(Based on performance)*	*Gas boiler for industry building* *Model name, company name, rated capacity, efficiency % (total calorific value, net calorific value), air flow rate of air blower, CMM, etc*

2.3 Korea On-line E-procurement System of Public Procurement Service

Korea On-line E-procurement System (www.g2b.go.kr) established as one of 11th projects for e-government in 2002 is the comprehensive e-procurement system to enable digitization of transactions between the government, public agencies and companies from purchase decision to payment (Seo, Jin-Wan (2009)), and the size of the public procurement market is 110 trillion KRW as of 2014 (Public Procurement Service (2015-2)) and it plays a role of saving national finance and improving technology competitiveness of companies by making procurement companies to provide quality service at a proper price. However, complicated procedures and unnecessary regulations of public procurement market have brought difficulties to startup companies to enter the procurement market, and excessive authentication requirements regarding products have become a burden to companies (Public Procurement Service (2015-2)). Also, the government procurement has public aspects such as the management of supply market considering the supply aspects, influence on the economy and industry due to public agency's consumption, professional support of procurement activities (Kidd (2007)) besides economic rationality, so the same product can be searched from Internet shopping web site at a lower price than the procurement price and procurement products are posted on Korea On-line E-procurement system for 1 year to 1 and a half year, there is a possibility that the price information may not be updated for a number of months rather than real-time update of price information, and it is the difference of government procurement from the private procurement based on economic rationality.

The materials information portal has no purpose of promoting public system targeting the whole nation or publicness aspect of purchase so that purchase behavior will be carried out according to economic rationality considering quality and price, and when materials production companies post the characteristics, performance and price information of products according to the standardized formats for data upload, consumers will be able to access the product information posted by companies by searching a desired condition.

3. Low energy Building Materials database

3.1 Range of Low energy Building Materials database Establishment

Low energy building materials database is established targeting materials and equipment systems such as insulation materials, windows, air conditioning equipment and boilers that influence the energy consumption of buildings, and the production information such as efficiency management machinery, equipment or materials, high-efficiency energy machinery, equipment or materials managed by Korea Energy Agency are also included. The following table shows the target and range of materials database establishment.

Table 2: Range of materials database establishment

Classification / source	Classification of establishment items			Number of items
	Materials	*Equipment*	*Electrical instrument*	
Public Procurement Service	*Insulation material, window, glass, interior finishing materials, exterior finishing materials, blind and shade, etc*	*refrigerator, air conditioner, ventilator, heat exchanger, heat pump, boiler, duct, etc*	*lighting fixture, lamp*	*165*
Prices information sheet	*Insulation materials, glass, window materials, block, roof materials, etc*	*boiler, air conditioner, refrigerator, heater, cooling and heating equipment, etc*	*lighting fixture, lamp*	*150*
Efficiency management machinery, equipment or materials	*Windows*	*Electric cooler, electric cold and hot water dispenser, household gas boiler, electric cooler and heater, gas water heater, electric heating fan, multi electric heat pump system*	*Incandescent lamp, fluorescent lamp, lamp with built-in ballast stabilizer*	*11*
High-efficiency energy machinery, equipment or materials		*heat recovery type ventilating system, gas/oil boiler for industry and buildings, pump, centrifugal type・screw type chiller, direct fired and absorptive cold and hot water dispenser, ventilator, centrifugal type air blower, etc*	*metalhalide lamp, embedded and fixed LED light fixture, light fixture for electrodeless fluorescent lamp*	*25*

3.2 Code system of low energy building materials database

In order to consider operation and management of materials database in future and enable linkage and operation with domestic building materials database later, the product list system and classification code of Public Procurement Service were introduced. The classification code was same with Public Procurement Service's code until sub-class, and the code for sub sub-class was recomposed according to the range of data to be established in this study. The established database for low energy building materials and equipment related insulation material, window, glass, refrigerator, boiler and lighting fixture was classified into 5 levels and 165 cases were coded. Table 3 shows a part of building material items.

Table 3: Code system of materials database (part)

Major Class		Middle Class		Minor Class		Sub-class		Sub Sub-class		Code name
CODE	ID	CODE	ID	CODE	ID	CODE	ID	CODE	ID	CODE

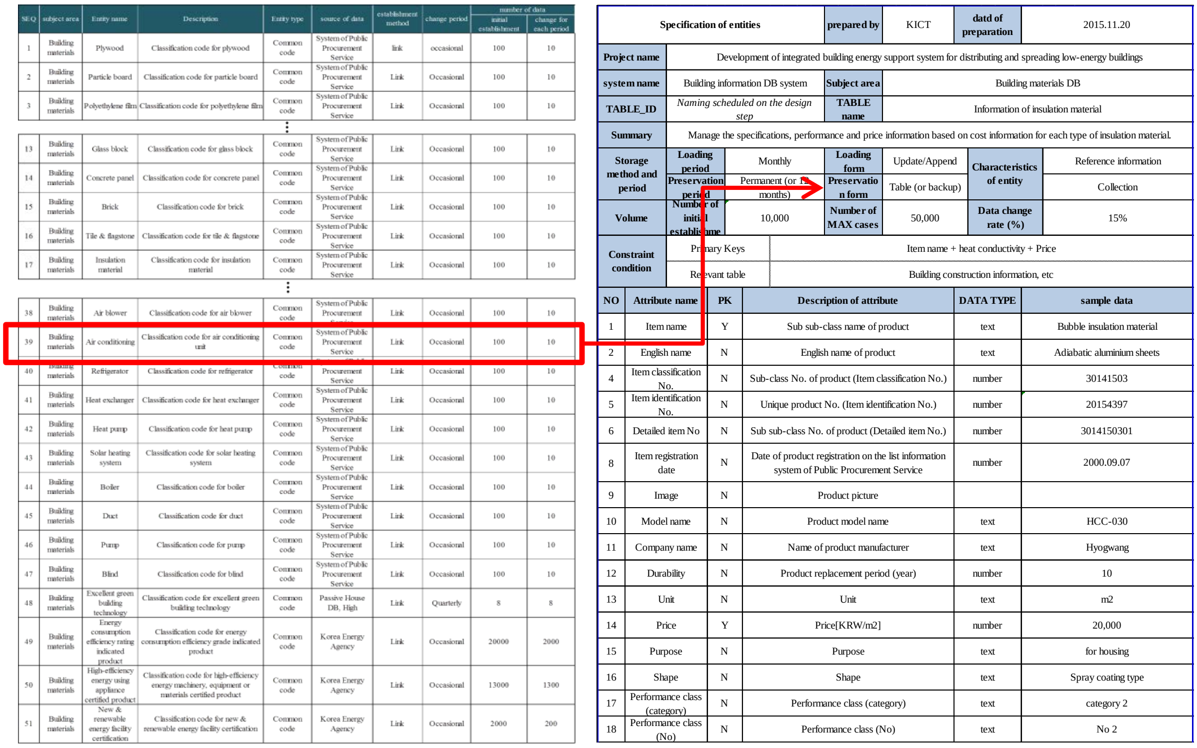
3.3 Establishment of low energy building materials database

Data modeling work is necessary for database establishment, and for this, the list and specification of entities are prepared and database is established according to the list and specification of entities. At first, an entity is tangible (eg: person, automobile, etc) and intangible (eg: hobby, trip, etc) information and it is defined as several related attributes which could explain and characterize the relevant information. The list of entities contains information regarding source of data, change period and number of materials for each data item to be established, so it is prepared to determine data area and capacity, and the specification of entities is prepared to define attributes related to data to be established and establish the relevant attribute information. Figure 2 shows the list and specification of entities in materials database.

Attribute information of materials database can be classified into general item and detailed information item for each product. Data was established with information that could include the product performance and characteristics information by collecting basic information such as product model name, image, company name, price and specifications in general item and collecting advisory opinions from employees of materials production and sales companies for the detailed information. The materials information data for materials information portal should be established to draw materials information search function as well as service result in economics section such as energy consumption reduction effect and cost recovery period according to the application of materials selected by consumers to buildings, so attribute information which influenced the building energy consumption was also included in the detailed information in addition to detailed information items generally used in the market, and the relevant detailed information items were composed based on input items of ECO2, which is building energy performance evaluation program used in domestic building energy efficiency rating system for calculating the rating. In case of detailed information items, the attribute of insulation material was defined with heat conductivity (W/m^2K), density (kg/m^3) and combustibility (burning time, burn length), and in case of boiler, it was defined with thermal efficiency (%), rated heat quantity (kW) and heating area(m^2).



SEQ	subject area	Entity name	Description	Entity type	source of data	establishment method	change period	number of data: initial establishment	number of data: change for each period

4. Discussion

For the establishment of low energy building materials database in this study, information is established under the cooperation with quasi-governmental agencies including prices information sheet, Public Procurement Service and efficiency management machinery, equipment or materials, but from the time of providing the service after materials information portal is completed, materials production and sales companies will upload product information. At this time, the information uploaded by companies show the price and quality of products in actual market, so it is the newest information, but companies will be responsible for the reliability of uploaded information. The verification and confirmation of information uploaded by companies are excluded from the concept of this study, but these elements are important items with regarding the usage frequency and satisfaction level of portal service from the viewpoint of consumers.

5. Conclusions

The purpose of this study is to provide reliable service of materials information portal through the establishment of public big data by collecting and integrating scattered low energy building materials and equipment data.

In the establishment of low energy building materials database in the country, there was almost no case of integrating scattered data based on the standardized data classification system and code. Therefore, data attribute items were extracted based on information highly used in the building market in this study in order to establish building materials database, and data standardization was carried out through the definition of attribute of such entities. It is possible to maintain accurate communication and data easily and improve operation efficiency in the portal development through the standardization of attribute definition by applying consistent input method (text or number), use of word and unit for materials of the same category.

The materials information portal can provide one stop service to users based on materials database under establishment in this study and real-time price information through voluntary upload of price information for establishing reasonable prices between materials production companies and allowing companies to register their products on the portal in future, so important verification process of standard system for portal data will be carried out continuously for searching, sharing and managing information from the position of portal users and developers and a study to improve users' satisfaction level such as GR certification (Good recycled), certification information such as environmental mark, review of legal obligations and recommendations before using materials and equipment and addition of user's review function will be carried out.

Abstract

As the environmental impacts of buildings have become more and more eminent, so too has the demand and need for specialized green property services. Green property services refer to operative real estate management services, including both property and facility management, which promote environmental, or green, aspect of the services. This study sets out to identify the possible future development paths associated with the expected rise in the demand of green property services in the future facilities market. The research uniquely utilizes a futures studies method in the context of facilities management. The futures wheel is a qualitative method based on expert opinions, and resembles structural brainstorming. With the futures wheel, different future elements and their possible influences can be identified, clarified and organized. The study finds that several outcomes, both beneficial and unfavourable, are possible in a future where green property services have become more common. The outcomes are classified based on the power to impact, namely, whether they are reached though the actions of the property service provider, or the client organisation. The identified first tier influences include surprisingly complex issues such as lack of expertise in the client organization, or poor occupant comfort resulting from effective energy management. On the other hand, highly positive influences, including intelligent buildings and saved natural resources are also identified as potential influences. The study is the first to employ the futures wheel method to facility services research, and provides a good foundation for further testing of the methods. Furthermore, the findings are a welcomed reminder to both researchers and practitioners of the intertwined and complex nature of sustainability issues within the built environment.

Keywords: commercial real estate, facilities management, futures wheel, green property services, sustainability

1. Introduction

The built environment is a significant cause of environmental impacts (UNEP 2007), and consequently, is often seen key in solving the environmental challenges set to our society. As the environmental impacts related to buildings have become eminent, the need and demand for specialized green property services are also growing. Green property services refer to operative real estate management services, including both property and facility management, which promote environmental, or green, aspect of the services. The role of facility management in building environmental performance is known to be crucial (e.g. Aaltonen et al. 2013, Kyrö et al. 2012, Määttänen et al. 2014a). Green property services can be defined as services that aim at reducing the negative impacts to the environment and human health, while simultaneously fulfilling the needs of occupant's and maintaining the property's condition and characteristics (Määttänen 2014a). In other words, green property services aim at both enhancing the environmental performance of the building and creating value to the end-customer. Määttänen (2014a) concludes that green property services are particularly useful when the end-user company lacks the appropriate resources for in-house environmental management. The increased demand for green property services has also been noted in market-based research, including a recent Green Market Study (Ramboll 2014), which estimates that green commercial facilities will become more common in the future. It has also been assessed that during the next few years property and user service companies will invest more in sustainable practices (KTI 2015). Interestingly, while the clients' green requirements are expected to increase, the willingness to pay premium for green services remains low (KTI 2014).

While it is clear that buildings affect the surrounding society, it should be noted that the surrounding society and different forces of change emerging in the real estate market environment have their own influence on the built environment and associated businesses. Regardless, property management practitioners are not generally aware of the future forces of change and their possible influences on the future development. In other words, practitioners may have to make decisions that will have far-reaching consequences for their business, without sufficient awareness and needed analysis of the possible future development in the field. This study sets out to identify possible future development paths associated with the expected rise in the demand of green property services in the future facilities market. The research uniquely utilizes futures studies methods in the context of facilities management. Futures studies have only recently been introduced in the context of real estate markets (Toivonen 2011; Toivonen and Viitanen 2015; Toivonen and Viitanen 2016). Moreover, previous futures studies based research from the property management field does not yet exist, to the best of the authors' knowledge.

According to previous studies environment pressure has been identified as a significant force shaping the future development of the commercial real estate market (Toivonen 2011; Toivonen and Viitanen 2015). Toivonen (2011) recognized the demand for green property services as a part of the environmental pressure set to the commercial real estate market and also as a phenomenon affecting the future market environment. For the purpose of this specific study, the increased demand in green property services is selected for further research through a method called the futures wheel. Based on Glenn (2009a) the futures wheel is a qualitative method based on expert opinions, and resembles structural brainstorming. With futures wheel different future elements and their possible influences can be identified, clarified and organized (Glenn 2009a). Through a better understanding of the potential future elements, practitioners would be more conscious and they would have better prospects of doing far-reaching and sustainable decisions about their business.

The study finds that several outcomes, both beneficial and unfavourable, are possible in a future where green property services have become more common. The first tier influences include surprisingly complex issues such as lack of expertise in the client organization, or poor indoor comfort resulting from effective energy management. On the other hand, highly positive influences, including intelligent buildings and saved natural resources are also potential. The first tier effects produce a number of second and third tier influences, resulting in possible development paths for the future of green property services. Each of these development paths is presented with a discussion on the positive and negative effects to ecological, social and economic sustainability. The outcomes are also classified based on the target of impact, namely, whether they affect the property service as a business, or the client organisation. The study is the first to employ the futures wheel method to facility services research, and provides good foundation for further testing of the methods. Furthermore, the findings are a welcomed reminder to both researchers and practitioners of the intertwined and complex nature of sustainability issues within the built environment.

The remainder of the paper is structured, as follows. The research methods are introduced in detail in the next section, due to the novelty of the application. The third section presents the findings of the research, and the fourth section discusses implications and limitation of the findings. Finally, the fourth chapter concludes the paper with suggestions for further research.

2. Research methodology

Property services are in a nascent state as a research field, and therefore the explorative, qualitative research methods offer a best methodological fit (Edmundson and McManus 2007). This study takes a novel approach and utilises futures studies methods for the property services research. Future studies methods have been found well-suited for investigating the future development of the commercial real estate market, which is continuously affected by several different external and internal forces (Toivonen 2011). According to Mannermaa (1999), the future is formed based on both conscious and unconscious thinking, planning, decision making and actions taking place in different parts of the society. The future is present in the current situation through several different possibilities that have not yet been realized (Malaska 1993; Seppälä & Kuusi 1993). These different possible development paths can be identified and analysed with the help of the futures wheel method. The following sub-section describes the futures wheel method in detail.

2.1 Futures Wheel

This study utilizes a method called the futures wheel to study the possible future influences caused of the expected increase in green property services. The futures wheel is a qualitative method based on expert opinions, and resembles structural brainstorming. With the futures wheel method, the possible future influences of a studied phenomenon can be identified and clarified. The possible influences are organized into the different circles of the wheel to present primary, secondary and tertiary influences of the phenomenon in question. These influences can be connected to an actor, or to an object (Glenn 2009a; Rubin 2002). The wheels presenting the possible influences can be formed via a joint session with external participants (Benckendorff 2007; Boujaoude 2000; Shakweer and Youssef 2007), or by an internal research team that collects data and organizes it into the wheels (Toivonen 2011; Rantasila 2015). According to previous experiences, the joint sessions allow the participants to interact and develop the presented ideas further together as a team (Benckendorff 2007). This was seen as a significant advantage, and thought to best serve the purpose of the study. Consequently, a joint session among experts was organized to investigate the possible future impacts of the green property services. The experts were chosen to represent built environment researchers, consultants, and green building professionals. Altogether 5 participants took part in the wheel formation session.

The researcher acted as facilitators for the session. In the beginning of the session, the facilitator briefly presented the investigated phenomenon as well as the futures wheel method to ensure that all participants understood what was going to happen during the session. After this preparatory phase, the name of the phenomenon under examination, namely, “Increasing the demand of green property services”, was placed in the middle of the wheel into the centre circle. Next, the facilitator asked the participants “What would happen if the demand for green property services would increase?”. After that, the participants started to discuss the possible influences and the facilitator simultaneously draw the wheel presenting their views. The facilitator encouraged the participants to think further by asking the possible secondary and tertiary influences caused by the influences described in the earlier stage. The primary influences were located on the first ring surrounding the centre circle, the secondary influences derived from the secondary influences were placed on the second ring and the tertiary influences caused by the secondary influences on the third ring. The influences were also connected to each other with lines to demonstrate connections between them. The participants discussed different potential influences and only the influences that were seen possible by all of the participants were chosen to the wheel (see Glenn 2009a). This procedure is seen to increase the reliability of the results. Finally the different rings surrounding the centre circle presented the possible primary, secondary and tertiary future influences of the increasing demand of green property services and their possible future development paths. An example of a future wheel is depicted in Figure 1.

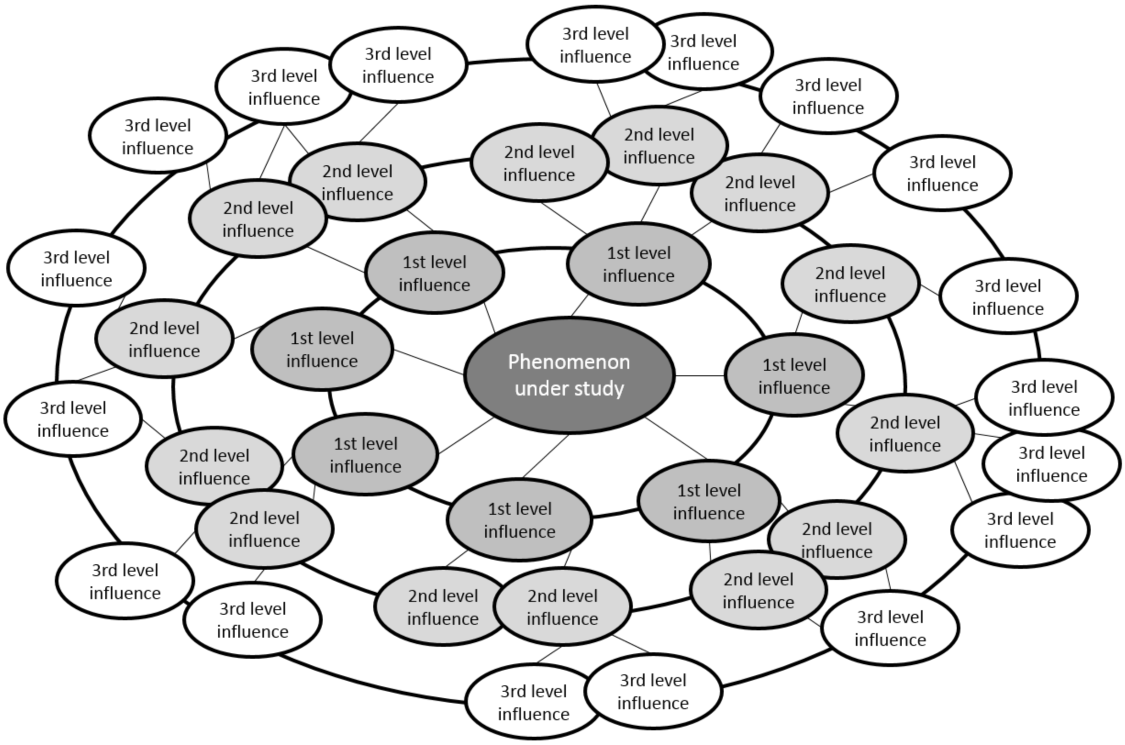

Figure 1: An example of a futures wheel

After the formation of the futures wheel, the influences on the outer rings are analysed and categorised into themes based on their context and power to impact, namely whether the influences concerned the service provider or the end-user. After this, the analysis process continued forward and the formed future themes divided as positive or negative. With the future studies it is possible to combine different value bases with different forecasts. This means that the desirability of different development paths can be evaluated (Bell 2003; Glenn 2009b; Mannermaa 1993). The desirability is derived from the values of every actor estimating the possible development. Futures researchers have presented some values that are universally seen desirable (Bell 2003; 2004; Malaska 1993) but in reality the desirability of different development paths might be viewed very differently among different stakeholders due to their individual position and characteristics (Heinonen 1993). However the desirability of different development paths is an essential part of the future studies while it determines the significance of the forecasts. If some development path is seen either very negative or very positive, it is considered more significant, than a development path that is seen indifferent (Linturi et al. 1998; Meristö 1993). This study analyzed the positivity and negativity of the influences from the service providers and the end-users point of view.

Bell (2003) argues that one of the aims of futures studies is the actualization of the development paths that are seen desirable. According to Bell, the results gained from futures studies should be exploited in practice, and the actors should try to steer the future development towards the desired direction. To be able to do that it is relevant to identify actors that are involved in different development paths. A development path that is seen very desirable will more likely be promoted than a development path that is irrelevant to the actor in question. Similarly, the involved actors will be more willing to try to prevent development paths that are seen very negative (Toivonen 2011). Due to this an analysis concerning the relevant stakeholders that will be affected by the development path and who possess the power of promoting or hindering the development, should be provided. As mentioned above, in this study the investigated stakeholders possessing this power are the service providers and the end-users. Next, the findings of the futures wheel on green property services are introduced.

3. Findings

This futures wheel on green property services identified influences up to the third-tier, and in one case also up to the fourth-tier. Altogether, the futures wheel generated 11 first-tier, 23 second-tier, four third-tier and one fourth-tier influences. The futures wheel on Green Property Services, as originally transcribed and translated from the Finnish research notes is presented as Figure 2.

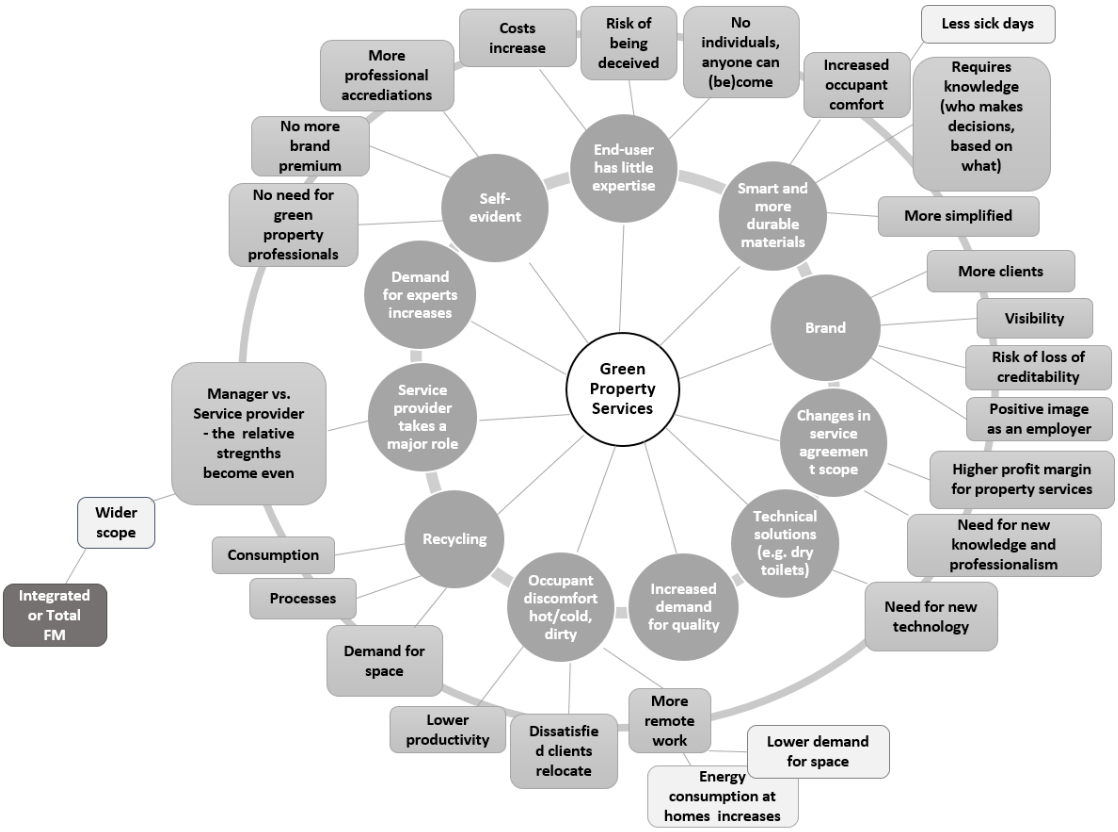

Figure 2: The Futures Wheel on Green Property Services

The first tier impacts were noted to be somewhat neutral, i.e. the influences do not have a clear negative of positive connotation. The identified first-tier influences comprise:

1. *Lack of expertise in end-user organisations*
2. *Changes in service agreement scope*

3. *Increased demand for quality of property services*
4. *The service provider's role is highlighted*
5. *The demand for green property professionals increases*
6. *Green property services become self-evident*
7. *Green brand for property management companies*
8. *Technical solutions*
9. *Recycling*
10. *Smart materials*
11. *Occupant discomfort: too hot, too cold, dirty*

During the second-tier however, even surprising negative potential influences were identified, along with the many positive potential impacts. However, this is considered to present an interesting contradiction that is truly beneficial for the analysis and identification of the future scenarios. Therefore the second-tier impacts were first categorised as either positive or negative. Furthermore, the direction of their impact was included in the analysis and divided into either end-user of service provider related impacts (See Table 1).

Table 1: The identified future themes

Power / *Direction*	*End-user*	*Service Provider*
Positive	*Lower space demand* *Occupant comfort and higher workplace productivity*	*Wider scope: Total FM*
Negative	*Cost and risk of outsourcing services* *Occupant discomfort and lower workplace productivity*	*No more demand for specialized services and no price premium for green services → green FM becomes obsolete*

Based on the findings, it may be argued that the key future scenarios of increased demand of green property services are related to the scope of services, i.e. are connected to the business logic of property services companies. Ultimately, this comes back to the discussion about integrated or total FM (Atkin and Brooks 2000), which was also included in the futures wheel as the final, fourth-tier outcome. Another related key finding is that green property services were thought to become the new norm. Määttänen et al (2014b) found that for example green cleaning could be on its way to becoming a standard service that the tenants expect to have, rather than a specialized green service. This is in line with a previous research. Määttänen et al. (2012) found that service providers should utilize their full potential and expertise better.

For the end-user or client organization, the major influences relate to the workplace productivity of the client organization, which is thought have both positive and negative outcomes. Low level of expertise in-house and outsourcing services were thought to carry some risks, and is therefore categorized as negative. On the other hand, lower space demand was also a result of the wheel, and this possible outcome is viewed as positive.

4. Discussion

This paper set out to identify the different future influences of green property services, which had previously been identified as one force of change in the current facility service field, with the help of an environmental scanning method (Toivonen 2011; Toivonen & Viitanen 2015). The potential influences of the green property services were then analyzed with the futures wheel method. Through analysis of the possible first, second and third tier influences identified with the wheel, the following potential future development paths for green property services were formed: 1) wider scope for service providers, 2) green property services becoming obsolete 3) increased workplace productivity 4) decreased workplace productivity 5) cost and risk of outsourcing services 6) lower cost from outsourced energy and space.

The results of the wheels were found to be partly contradictory with each other. While this contradiction complicates the interpretation of the possible future influences, it gives valuable information concerning the inner conflicts that the phenomenon may possess. Glenn (2009) has seen this as a special advantage of the futures wheel method as it reveals the potential internal and external conflicts that could remain unnoticed. Likewise, Toivonen (2011) recognized this challenge to be an opportunity to increase a holistic awareness of the possible development paths of the phenomenon under study. This in turn allows the actors to prepare themselves for the needed actions to be able to cope with and steer the development of the future conditions. This study divided into either end-user of service provider related influences and analysed the desirability of the influences. This may help the relevant stakeholders to take actions to steer the development towards the desired future development.

This research contributes to the scientific body of knowledge in facilities management by introducing a novel research method. The future wheel as a research method is especially useful when structuring the relationships between different phenomena and influences due to the illustrative nature of the wheels. The method was rather easily applied and enabled structuring the future development paths and possible influences. The findings are in line with previous experiences concerning the method (Benckendorff 2007; Boujaoude 2000; Glenn 2009a; Toivonen 2011; Toivonen & Viitanen 2016). Outside the research field, the wheels could allow practitioners to foresee the potential influences proactively. Furthermore, by recognizing the wide range of different influences, it is possible to analyse who will be affected by the different development directions, and who are the actors possessing the power to steer the development direction. Furthermore, the results allow practitioners to estimate the wanted and unwanted development paths from their own point of view, and possibly form coalitions with other likeminded practitioners to enhance the desired development path. With the connection between forces and influences, practitioners can estimate which development paths are wanted or unwanted, and direct their actions towards the wanted development paths or trying to prevent the unwanted ones, or altogether examine if their future targets are against or in favour of the possible future development and future theme.

4.1 Evaluation of research

According to Mannermaa (1993), it is not possible to analyse the success of a futures study by investigating the fulfilment of presented predictions, as the future does not exist as such in the current situation, and the presented predictions might affect the actualization of the foreseen prediction. For example market actors may change their behaviour after acknowledging the ongoing development thanks to the predictions and consequently change the development path. Due to these reasons the success of futures studies should be analyzed by evaluating the possibility of the presented development paths (Gordon 1989; Mannermaa 1993; Pantzar 1993). Therefore, when evaluating this study, it has to be analysed whether the presented influences could actually occur when taking into account the current knowledge of the present situation.

This study selected only the influences that were jointly agreed by the participants to be analysed in the final wheels, in order to ensure that the results would comprehensively present the possible future influences of the green property services. However, as previously stated by many researchers (Gordon 1992; Mannermaa 2004; Naisbit 1984; Niiniluoto 1993), the presented predictions cannot be perfect and include all the possible development paths. Something will always remain unrevealed. For example some of the influences may have falsely been seen impossible according to current knowledge, and therefore left out from the wheels. On the other hand, the wheels may contain influences that turn out to not be possible in the future. For example technological advancement or legal restrictions might have this kind of effect. Most importantly, it should be noted that the futures wheel method is highly dependent on the participants forming the wheels, as well as on the facilitators guiding the participants to exercise future thinking. This study pursued to include specialists representing the field of sustainable built environment, roles ranging from researcher, consultants, architect and advisor. However, it can be stated that the variety of participants could have been wider and the number of participants could have been higher to better ensure the coverage of the possible future influences. Similarly, the analysis over the desirability of the influences could be developed further. For the purpose of this study, this task was conducted by the researchers but it can be argued if the positivity and negativity should be analysed by the stakeholders i.e. the service providers and the end-users themselves.

Regardless of the aforementioned uncertainties inherent to the futures studies methods, it may be argued that the future wheel method is a suitable tool for investigating unknown future development paths, such as the future development of facility services.

5. Conclusions

The study is the first to employ the futures wheel method to facility services research, and provides a good foundation for further testing of the methods. The findings, which identify a number of contradictory positive and negative potential influences, are a welcomed reminder to both researchers and practitioners of the intertwined and complex nature of sustainability issues within the built environment. A very good example is occupant comfort, which is seen to be affected both positively and negatively by Green FM. Further research could focus on finding more potential forces of change to be analysed with the future wheel, or analysing the now identified potential influences on a more detailed level. As the study identified a number of conflicting and even detrimental potential influences of green property services, both to the environment and FM as a profession, the potential negative influences in particular should receive more research attention in the future.

Institute for Industrial Production (IIP), Karlsruhe Institute of Technology (KIT)
Email: anna.kuehlen@kit.edu

Abstract

Nowadays, due to globally increasing building densities in cities, demolition works are an inherent part of construction. And they are focal activities related to life-cycle-oriented management of construction materials, which aims at drastically reduce the deployment and consumption of primary non-renewable construction materials. To give an overview on related worldwide existing activities, the state of the art of demolition and of reuse and recycling of construction materials is summarized in a report of selected countries based on reports of these countries. Within this report, first typical structures of the demolition and recycling industry in different countries, typical phases of demolition and recycling processes and involved stakeholders with their characteristic competencies are described. Secondly, leading companies, associations and research institutions in selected countries are outlined. Leading processes are identified by distinguishing between design processes for deconstruction, deconstruction processes on-site and innovative on-site and off-site recycling processes. Thirdly, challenges related to demolition and reuse and recycling of construction materials are identified and analysed in terms of technical, economic, ecologic, organizational and educational and political/legal challenges. Finally, single, country specific, already existing approaches to meet these challenges are identified.

Keywords: State of the art, deconstruction, life-cycle-oriented management, construction materials, reuse and recycling

1. Introduction

Nowadays, due to globally increasing building densities in cities, demolition works are an inherent part of construction. Furthermore, demolition works are focal activities related to life-cycle-oriented management of construction materials, which aims at drastically reduce the deployment and consumption of primary non-renewable construction materials. To give an overview on related worldwide existing activities, the state of the art of demolition and of reuse and recycling of construction materials is summarized in the following report. For this overview, the state of the art in selected countries is analysed based on reports of these countries, firstly by describing typical structures, processes and stakeholders of the demolition and recycling industry. Secondly, by outlining leading companies, associations and research institutions as well as leading processes. Thirdly, by identifying and examining technical, economic, ecologic, organizational and educational and political/legal challenges. Finally, by identifying single, country specific and already existing approaches to meet these challenges.

1.1 Description of the demolition sector

The demolition sector[1] is by no means homogenous and currently displays a wide diversity of sophistication levels, varying within and between regions and countries. Diverse stakeholders, such as clients, planning engineers, emission and contamination experts, decontamination companies, demolition companies, authorities and neighbours, are involved in and/or effected by the demolition process. These stakeholders have different interests and influences on the demolition project. Related to building types, surrounding conditions and sometimes hazardous substances of the building usage phase, the fields of activities are diverse and therefore, a variety of different usually small- and medium-sized enterprises dominate the demolition sector. The demolition sector is assigned to code F43.1 (demolition and site preparation) within the industry branch classification scheme NACE (EC - NACE (2010)). In 2012 nearly 170.000 enterprises of this sector represent 5% of all construction activities in the EU. 95% of these enterprises employ less than 10 persons and only 3.5% have more than 50 employees (EC – Eurostat (2015)).

1.2 Processes of construction materials management

The demolition process of buildings and infrastructures is at least as complex and sophisticated as the construction process. Figure 1 (own representation based on DA (2015)) shows the classical process steps, starting with building auditing to plan preliminary decontamination and site clearance followed by demolition, crushing, sorting, reprocessing and recycling processes. Furthermore, involved stakeholders are assigned to each project stage.

In the auditing and planning stage, the client, planning engineers and depending on the type of structure also authorities formulate the tender specifications. The decontamination and demolition companies audit the structure themselves and bid for the project. During auditing and planning, national guidelines are applied depending on the gross volume and characteristics of the building/infrastructure to be deconstructed.

In the preparation and demolition stages, the accepted company plans the previous steps. Depending on the type of structure and available space onsite, different demolition, crushing and sorting techniques are applied to disassemble building elements and break the material into transportable or reusable pieces. During preparation and demolition, legal regulations regarding occupational health and safety, including impact limits, protection measures, etc. have to be applied. Furthermore, national guidelines are applied regarding best practices in demolition,

[1] In parts of the world, where resource recovery is the standard, the term “demolition” is used synonymously with the terms deconstruction, dismantling and disassembly. But for most of the world, demolition with no thought to materials recovery is the standard and deconstruction is the best practice exception related to the careful disassembly/dismantling of buildings to recover materials for reuse. Hence, in the following, the term demolition is used in general terms.

namely deconstruction, processing and sorting such as in the German standard DIN 18007:2000-05. Especially, the prevalent type of construction, the prevalent materials, space availability, available (state-of-the-art) resources and entrepreneurial calculus determine the choice of technologies and applied resources in deconstruction, crashing, sorting and recycling processes. Within this context, waste fraction types and recycling paths/quotas of deconstruction materials are usually not predefined. Hence, the definition is left to the demolition companies, which face the challenge to constantly produce recycling material of good quality under changing and often not influenceable conditions.

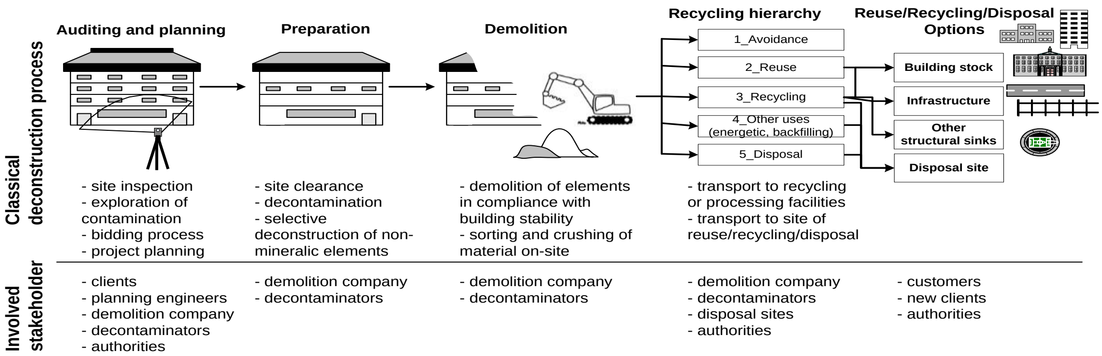

Figure 1: Classical demolition and reuse/recycling process (own representation based on DA (2015))

In the reuse, recycling and disposal stages, materials are reprocessed, crushed, sorted, etc. to gain recycling materials of defined quality (e.g. defined in the German standard DIN 4226-100 for recycled aggregates) or to be classified into waste fractions of different qualities and prices. During reuse/recycling a plethora of legal, often regionally differing regulations have to be applied. These regulations address material quality and waste classifications, contamination limits regarding soil and health protection, allowed reuse/recycling options as well as transportation allowances. Major potential customers of recycling materials are authorities (for instance, regarding road works) and individual consumers with resource-saving attitudes.

1.3 Level of professional competency and business processes

Depending on the diversity of involved stakeholders, education in the demolition sector encompasses very different professions and degrees. Table 1 (own representation based on DA (2015)) gives an overview of the most common professional educations related to the type of stakeholders involved in the demolition process.

Table 1: Overview on educational degrees in the demolition and recycling industry (own representation based on DA (2015))

Stakeholder	***Profession/degree***
Planning engineer	*Architect, civil engineer*
Demolition site manager	*Civil engineer*
Health and safety coordinator	*Architect, civil engineer*
Foreman	*Master craftsmen*
Equipment operator	*Operator*

Skilled worker	*General training related to construction work (brick layer, concrete worker) and special training related to demolition work*
(Unskilled) worker	-

In organizational terms, the demolition process (especially the deconstruction process) has project character, similarly to the “normal” construction process. A client, who is usually consulted by a planning engineer, calls for tenders and then accepts an offer of one demolition company. This company either performs the actual demolition process on site itself or acts as a main contractor and assigns single tasks to subcontractors and experts. Usually, for each demolition project new project teams are created. The engagement of subcontractors often follows long-term cooperation/alliances. In general, at least the removal of hazardous materials is done by a subcontractor. Following demolition on site, deconstruction material is landfilled or recycled, either by the demolition company itself or a special recycling company (DA (2015)).
Demolition works are one of the most dangerous jobs in the construction sector, due to confined space on site, parallel work, time pressure, hazardous materials, harmful impacts, such as noise and dust, as well as regularly unpredictable building statics and working conditions (Gabriel et al. (2010)). Hence, for instance in Germany a coordinator for safety and health matters has to be employed by the client by law, according to the construction site ordinance (BaustellV (2004)), when more than one contractor (including subcontractors) work on site. This coordinator consults the client, the planning engineer, the demolition company and subcontractors during planning and execution of the demolition process (§3, BaustellV (2004)).
Furthermore, often a waste concept has to be designed beforehand, where created debris /recycling material has to be quantified and their disposing has to be clarified. For instance, in Germany demolition companies can receive a quality label for deconstruction works by fulfilling defined and regularly controlled quality criteria, for example related to education and skills of employees and subcontractors as well as quality of equipment (RAL (2015)). In Germany, Denmark and Netherlands, paper-based documentation of buildings is dominating (Brewer and Mooney (2008)). Project progress and performance is almost daily reported to the project planner and controller via tablet or cell phone.

2. Leading Edge

2.1 Leading construction materials management industries

To identify leading companies in the demolition industry, it is suitable to look at major demolition tasks and respective leading companies performing these tasks. Tasks can be roughly divided into two main tasks levels: On the one hand, demolition is performed on different structure types, including complex bridges and viaducts, high-rise buildings, and industrial and chemical plants. On the other hand, demolition works are carried out in different sectors, such as the energy, petrochemical, infrastructure, education, industrial, residential and commercial sector. Related to demolition works in different sectors, there are some synergies with residential recycling, waste-to-energy and landfill gas-to-energy facilities. The tasks within these levels can overlap. As, the industry is scattered into small and medium sized enterprises, an overview of leading companies in the industry according to the outlined tasks is difficult.

Nevertheless, Table 2 (own representation based on the scope of this report) shows a selection of leading companies and associations of different countries based on the scope of this report.

Table 2: Selection of leading demolition and material recycling companies and associations based on the scope of this report

Country of origin	***Company/institutions name***
Australia	*Instant Waste Management; Liberty Industrial (Deconstruction, Remediation & Civil); National Federation of Demolition Contractors*
Canada	*Milestone Project Management, Winnipeg; 3R Demolition*
Germany	*German Demolition Association (Deutscher Abbruchverband e.V., DA); RAL Community of Goods for Demolition Works (RAL Gütegemeinschaft Abbrucharbeiten); Gesamtverband Schadstoffsanierung e.V.*
Netherlands	*Nihot air recycling technology*
UK	*Absolute Demolition Ltd*
US and Canada	*National Demolition Association; Building Materials Reuse Association; Construction Materials Recycling Association*

2.2 Leading life-cycle-oriented management of construction processes

Common practices of deconstruction[2] of the demolition industry are (DA (2015), VDI/GVSS 6202 (2012)): Identification of hazardous materials, such asbestos; inventory listing of materials to determine, where each item will be sent; structural deconstruction starting from the roof down to the foundations and non-structural deconstruction, such as the removal of appliances, windows, doors and other finishing materials, which can be marketable components. Further practices are: cleaning and/or refinishing of materials after separation from the structure to increase the material value; secure and dry storage of dismantled building components; location of material salvage, encompassing non-profit reclamation yards and dismantling contractors and on-site or off-site recycling of materials that cannot be salvaged or taken to landfills. Additional aspects, which are considered especially by leading stakeholders of the demolition industry, are: Bespoke risk assessments and method statements, compliance with standards (such as BS6187:2011) - safe systems of work, state-of-the-art, high-tech demolition specific equipment, experienced and trained personnel and best practice and innovation.
Diverse processes of deconstruction and recycling related to these practices and additional aspects and up-to-date leading deconstruction and recycling processes based on the scope of this report are outlined in Table 3 (own representation based on the scope of this report).

Table 3: Overview on life-cycle-oriented construction material management processes based on the scope of this report

Main process	***Description/content/application***
Integrated design & Design for deconstruction processes	- *Upstream approach considering deconstruction during their design process.* - *Combination of simple construction methods with high-grade, durable materials with visible separation layers and mechanical fasteners such as bolts.* - *Deconstruction, Separation and disassembly of components / building elements.* - *Standardized materials, inventory systems for reclaimed materials (via bar codes,*

[2] The careful disassembly/dismantling of buildings to recover materials for reuse.

	RFID,GIS) and their consistent application throughout the project. - *Avoidance of difficult construction methods and materials in deconstruction such as nails and adhesives.* - *Avoidance of hazardous materials altogether.* - *Avoidance of mixed material grades to improve material quality.* - *Saving/ Adaptation of existing structures to new needs.* - *Modular building elements, that can be reconfigured as desired.*
Deconstruction processes	- *3D Demolition Simulation software for Extreme Loading for Structures (ELS) (Roaf et. al (2004)): used to model the collapse of a building. ELS software is based on structural-analysis using the applied element method (AEM) for tracking of cracks, separation of elements, and collapse of structures under extreme loads. ELS provides demolition scenarios and predictions for structural defects resulting from seismic activity as well as visualisation of forecasted structural responses.* - *Smartwaste software tool developed by Building Research Establishment (BRE): assists in preparing and implementing Site Waste Management Plans and waste monitoring reporting. It includes a calculator for costs of embodied energy of waste and labor for waste disposal as well as an interactive map to find for instance waste management facilities, recycling sites, transfer stations and landfill sites as well as local reclaimed and recycled products and equipment for recycling and reprocessing.* - *ERO Concrete Recycling robot: conceptual robotic concrete demolition machine that also bags the crushed aggregate in the same process.*
Innovative on-site and off-site recycling processes	- *Full site assessment: identifying decommissioning requirements and other separate assets to maximizing material value and recovery. Maintaining the building stability during structural separation and alterations.* - *Soft Stripping: non-structural deconstruction of internal fixtures and fittings.* - *Single stream recycling plants (off-site): sort waste materials.* - *Diversion and Recycling Tracking (DART): online tool used to process waste materials from building construction and demolition sites.* - *Separate handling of building plastic and electronic waste.*
Separation processes	- *Vacuum systems for separating film plastics.* - *Magnets for recovering ferrous metal.* - *Optical-sorting technologies for separating wood and aluminium. For instance, cameras and laser technologies to identify and sort objects and materials.* - *Vibratory Screens for separating small stones and rocks, for reuse in construction.* - *Gypsum plasterboards and blocks "closed-loop" recycling: recycling process separates gypsum from paper and both materials return in their original products.* - *MRF (Material Recovery Facility): can recycle between 80 to 90 % of construction demolition waste in a single skip bin system. The facility extracts a variety of materials, including sand, wood, metals, brick, light materials and concrete by a rotating electro magnet, a flotation tank, a sand oscillation screen and a shredder.* - *Bulk Handling Systems (BHS): automated process for sorting significant percentages of the C&D material which is made up of small pieces. Eliminates inefficient hand sorting and keeps these materials out of the landfill.* - *Air Separation Technology (AST): accurately separates rock, wood and light material by using air pressure, wind shifters and drum separators.* - *Pneumatic vacuum systems for small rubble removal (intended for post disaster demolition process) and commercial machinery used currently only for loose stone such as roof ballast.* - *Brick mortar removing power tools that plane or grind off the mortar.* - *De-nailing guns for nail removal.*

3. Perceived Problems and Challenges and Potential Solution Approaches
